PATENT APPLICATION**

**APPLICATION  
FOR  
UNITED STATES LETTERS PATENT**

TO ALL WHOM IT MAY CONCERN

Be it known I,

**Scott E. Hrastar** of 2125 Noblin Ridge Trail, Duluth, Georgia 30097, U.S.A., a citizen of the United States of America.

have invented new and useful improvements in

**SYSTEMS AND METHODS FOR ADAPTIVE MONITORING WITH  
BANDWIDTH CONSTRAINTS**

for which the following is a specification.

**ATTORNEY DOCKET NO. 093615600016**

**SYSTEMS AND METHODS FOR ADAPTIVE MONITORING WITH  
BANDWIDTH CONSTRAINTS**

**BACKGROUND**

5           The present invention is directed to systems and methods for securing wireless computer networks. More specifically, without limitation, the present invention relates to systems and methods for adaptively scanning for wireless communication.

          The Internet is a global network of connected computer networks. Over the last several years, the Internet has grown in significant measure. A large number of  
10       computers on the Internet provide information in various forms. Anyone with a computer connected to the Internet can potentially tap into this vast pool of information.

          The information available via the Internet encompasses information available via a variety of types of application layer information servers such as SMTP (simple  
15       mail transfer protocol), POP3 (Post Office Protocol), GOPHER (RFC 1436), WAIS, HTTP (Hypertext Transfer Protocol, RFC 2616) and FTP (file transfer protocol, RFC 1123).

          One of the most wide spread methods of providing information over the Internet is via the World Wide Web (the Web). The Web consists of a subset of the computers  
20       connected to the Internet; the computers in this subset run Hypertext Transfer Protocol (HTTP) servers (Web servers). Several extensions and modifications to HTTP have been proposed including, for example, an extension framework (RFC 2774) and authentication (RFC 2617). Information on the Internet can be accessed through the use of a Uniform Resource Identifier (URI, RFC 2396). A URI uniquely specifies the  
25       location of a particular piece of information on the Internet. A URI will typically be composed of several components. The first component typically designates the protocol by which the address piece of information is accessed (e.g., HTTP, GOPHER, etc.). This first component is separated from the remainder of the URI by a colon (':'). The remainder of the URI will depend upon the protocol component. Typically, the  
30       remainder designates a computer on the Internet by name, or by IP number, as well as a more specific designation of the location of the resource on the designated computer. For instance, a typical URI for an HTTP resource might be:

**ATTORNEY DOCKET NO. 093615600016**

`http://www.server.com/dir1/dir2/resource.htm`

where `http` is the protocol, `www.server.com` is the designated computer and `/dir1/dir2/resource.htm` designates the location of the resource on the designated computer. The term URI includes Uniform Resource Names (URN's) including  
5 URN's as defined according to RFC 2141.

Web servers host information in the form of Web pages; collectively the server and the information hosted are referred to as a Web site. A significant number of Web pages are encoded using the Hypertext Markup Language (HTML) although other encodings using SGML, eXtensible Markup Language (XML), DHMTL or XHTML  
10 are possible. The published specifications for these languages are incorporated by reference herein; such specifications are available from the World Wide Web Consortium and its Web site (`http://www.w3c.org`). Web pages in these formatting languages may include links to other Web pages on the same Web site or another. As will be known to those skilled in the art, Web pages may be generated dynamically by a  
15 server by integrating a variety of elements into a formatted page prior to transmission to a Web client. Web servers, and information servers of other types, await requests for the information from Internet clients.

Client software has evolved that allows users of computers connected to the Internet to access this information. Advanced clients such as Netscape's Navigator and  
20 Microsoft's Internet Explorer allow users to access software provided via a variety of information servers in a unified client environment. Typically, such client software is referred to as browser software.

Electronic mail (e-mail) is another wide spread application using the Internet. A variety of protocols are often used for e-mail transmission, delivery and processing  
25 including SMTP and POP3 as discussed above. These protocols refer, respectively, to standards for communicating e-mail messages between servers and for server-client communication related to e-mail messages. These protocols are defined respectively in particular RFC's (Request for Comments) promulgated by the IETF (Internet Engineering Task Force). The SMTP protocol is defined in RFC 821, and the POP3  
30 protocol is defined in RFC 1939.

**ATTORNEY DOCKET NO. 093615600016**

Since the inception of these standards, various needs have evolved in the field of e-mail leading to the development of further standards including enhancements or additional protocols. For instance, various enhancements have evolved to the SMTP standards leading to the evolution of extended SMTP. Examples of extensions may be  
5 seen in (1) RFC 1869 that defines a framework for extending the SMTP service by defining a means whereby a server SMTP can inform a client SMTP as to the service extensions it supports and in (2) RFC 1891 that defines an extension to the SMTP service, which allows an SMTP client to specify (a) that delivery status notifications (DSNs) should be generated under certain conditions, (b) whether such notifications  
10 should return the contents of the message, and (c) additional information, to be returned with a DSN, that allows the sender to identify both the recipient(s) for which the DSN was issued, and the transaction in which the original message was sent.

In addition, the IMAP protocol has evolved as an alternative to POP3 that supports more advanced interactions between e-mail servers and clients. This protocol  
15 is described in RFC 2060.

The various standards discussed herein by reference to particular RFC's are hereby incorporated by reference herein for all purposes. These RFC's are available to the public through the Internet Engineering Task Force (IETF) and can be retrieved from its Web site (<http://www.ietf.org/rfc.html>). The specified protocols are not  
20 intended to be limited to the specific RFC's quoted herein above but are intended to include extensions and revisions thereto. Such extensions and/or revisions may or may not be encompassed by current and/or future RFC's.

A host of e-mail server and client products have been developed in order to foster e-mail communication over the Internet. E-mail server software includes such  
25 products as sendmail-based servers, Microsoft Exchange, Lotus Notes Server, and Novell GroupWise; sendmail-based servers refer to a number of variations of servers originally based upon the sendmail program developed for the UNIX operating systems. A large number of e-mail clients have also been developed that allow a user to retrieve and view e-mail messages from a server; example products include  
30 Microsoft Outlook, Microsoft Outlook Express, Netscape Messenger, and Eudora. In

**ATTORNEY DOCKET NO. 093615600016**

addition, some e-mail servers, or e-mail servers in conjunction with a Web server, allow a Web browser to act as an e-mail client using the HTTP standard.

As the Internet has become more widely used, it has also created new risks for corporations. Breaches of computer security by hackers and intruders and the potential  
5 for compromising sensitive corporate information are a very real and serious threat.

Wireless Local Area Networks (WLANs) offer a quick and effective extension of a wired network or standard local area network (LAN). FIG. 1 depicts a typical LAN 190 including both wired and wireless components. The wired component depicted in FIG. 1 includes a variety of connected systems including local servers 120,  
10 local clients 130 and network accessible data storage components 110. By simply installing access points 180A, 180B to the wired network (e.g., Ethernet 150 and router 140), personal computers and laptops equipped with WLAN cards 170A, 170B can connect with the wired network at broadband speeds.

Over the last few years, most deployments of WLANs have conformed to the  
15 Institute of Electrical and Electronics Engineers (IEEE) 802.11b standard that operates over the unregulated 2.4 GHz frequency spectrum. The 802.11b standard offers connectivity of up to 11 Mbps – fast enough to handle large e-mail attachments and run bandwidth-intensive applications like video conferencing. While the 802.11b standard now dominates the WLAN market, other variations of the 802.11 standard, such as  
20 802.11a, 802.11g, and supporting standards such as 802.1X, are being developed to handle increased speeds and enhanced functionality. WLAN vendors have committed to supporting a variety of standards. The various 802.11 standards developed by the IEEE are available for download via URL:

<http://standards.ieee.org/getieee802/802.11.html>; these various standards are hereby  
25 incorporated by this reference herein.

As businesses connected their LANs to the Internet 160, they installed firewalls  
145 to protect their local networks and act as security gates to fend off unauthorized traffic coming from the Internet's information highway such as potential hacker 135. The mobility of air-bound, wireless networks creates security concerns where threats  
30 can come from any direction and are not limited to the wired infrastructure. Established security practices of guarding a few wired entry points to the network are

**ATTORNEY DOCKET NO. 093615600016**

no longer effective. A firewall 145 may effectively deter an attack from a wired hacker 135 via the Internet 160; however, wireless hackers 195A, 195B typically enter the LAN 190 through access points 180A, 180B that are already behind the firewall 145. Companies must constantly monitor their airwaves to survey wireless activity and  
5 guard against intruders.

Because wireless communication is broadcast over radio waves, eavesdroppers 195A, 195B who merely listen to the airwaves can easily pick up unencrypted messages. Additionally, messages encrypted with the Wired Equivalent Privacy (WEP) security protocol can be decrypted with a little time and easily available hacking tools.  
10 These passive intruders put businesses at risk of exposing sensitive information to corporate espionage.

The theft of an authorized user's identity poses one the greatest threats. Service Set Identifiers (SSIDs) that act as crude passwords and Media Access Control (MAC) addresses that act as personal identification numbers are often used to verify that clients  
15 are authorized to connect with an access point. However, existing encryption standards are not foolproof and allow knowledgeable intruders to pick up approved SSIDs and MAC addresses to connect to a WLAN as an authorized user with the ability to steal bandwidth, corrupt or download files, and wreak havoc on the entire network.

Outsiders who cannot gain access to a WLAN can none-the-less pose security  
20 threats by jamming or flooding the airwaves with static noise that causes WLAN signals to collide and produce CRC errors. These Denial-of-Service (DoS) attacks effectively shut down the wireless network in a similar way that DoS attacks affect wired networks.

Careless and deceitful actions by both loyal and disgruntled employees also  
25 present security risks and performance issues to wireless networks with unauthorized access points, improper security measures, and network abuses. Because a simple WLAN can be easily installed by attaching a \$80 access point to a wired network and a \$30 WLAN card to a laptop, employees are deploying unauthorized WLANs or peer-to-peer wireless connections 175 when IT departments are slow to adopt the new  
30 technology.

**ATTORNEY DOCKET NO. 093615600016**

Incorrectly configured access points are an avoidable but significant hole in WLAN security. Many access points are initially configured to broadcast unencrypted SSIDs of authorized users. While SSIDs are intended to be passwords to verify authorized users, intruders can easily steal an unencrypted SSID to assume the identity of an authorized user.

Authorized users can also threaten the integrity of the network with abuses that drain connection speeds, consume bandwidth, and hinder a WLAN's overall performance. A few users who clog the network by trading large files such as MP3 audio or MPEG video files can affect the productivity of everyone on the wireless network.

The systems and methods as disclosed herein provide solutions to these and other security and/or management issues associated with WLANs and/or encrypted computer networks.

**SUMMARY**

The present application is directed to methods for adaptively monitoring a wireless network with bandwidth constraints. A typical system includes a system data store (SDS) and a system processor. The SDS stores data needed to provide the adaptive monitoring functionality. The SDS may include multiple physical and/or logical data stores for storing the various types of information. Data storage and retrieval functionality may be provided by either the system processor or data storage processors associated with, or included within, the SDS. Some implementations can further include one or more wireless receivers that monitor wireless transmissions.

The system processor is in communication with the SDS via any suitable communication channel(s); in implementations including one or more wireless receivers, the system processor is in communication with the one or more wireless receivers via the same, or differing, communication channel(s). The system processor may include one or more processing elements that provide and/or support the desired adaptive monitoring functionality. In some cases, the system processor can include local, central and/or peer processing elements depending upon equipment and the configuration thereof.

**ATTORNEY DOCKET NO. 093615600016**

Accordingly, one method of adaptive scanning with bandwidth constraint includes a variety of steps that may, in certain embodiments, be executed by the environment above or be stored as computer executable instructions in and/or on any suitable combination of computer-readable media. Data is received from a wireless node. When a bandwidth constraint is satisfied, the received data is buffered for subsequent transmission to a monitoring processor. If the bandwidth constraint is not satisfied, the received data can be immediately forwarded to the monitoring process.

In some implementations, downsampling of the data stream can occur to meet the target bandwidth constraint. In addition, or instead, received data can be discarded and/or aggregated to conserve buffer space.

When the bandwidth constraint is no longer satisfied the buffered data is transmitted to the monitoring process.

Additional advantages of these systems and methods will be set forth in part in the description which follows, and in part will be obvious from the description, or may be learned by practice. The advantages will be realized and attained by means of the elements and combinations particularly pointed out herein. It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory only and are not intended as restrictive.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate various aspects of the disclosed systems and methods and together with the description, serve to explain and/or exemplify their principles.

**FIG. 1** graphically depicts a typical LAN with both wired and wireless components.

**FIGs. 2A-E** graphically depicts LANs incorporating various preferred configurations.

**FIG. 3** is a flow chart of a multi-dimensional wireless intrusion detection process.

**FIG. 4** is a flow chart of an example multiple input wireless intrusion detection process including multiple input correlation and long-term data fusion.

**ATTORNEY DOCKET NO. 093615600016**

**FIG. 5** is a flow chart of an exemplary dynamic channel change active defense process that includes a honeypot trap.

**FIGs. 6A-B** are flow charts of example station identification and location mapping processes.

5        **FIGs. 7A-C** are diagram depicting exemplary architectures for sensor devices.

**FIGs. 8A-B** are flow charts depicting an exemplary security data collection process.

**FIG. 9** is a flow chart depicting steps in an exemplary wireless network topology tracking process.

10       **FIG. 10** is a flow chart depicting an automated wireless network policy enforcement process.

**FIG. 11** is a flow chart depicting an adaptive scanning process.

**FIG. 12A-B** is a figure depicting a sample visualization of a wireless network topology.

15       **FIG. 12A1** is a larger rendering of the left panel of FIG. 12A.

**FIGs. 13A1, 13A2, 13B1 & 13B2** depict sample screens providing interfaces for configuration of automated policy enforcement.

**FIG. 13A1a** is a larger rendering of the left panel of FIG. 13A1.

**FIG. 14** depicts an exemplary interface for configuring a default or baseline  
20    scan pattern.

**FIG. 15** is a flow chart depicting an adaptive monitoring process.

**FIG. 16** is a flow chart depicting adaptive location tracking process.

**FIG. 17** is a flow chart depicting a process for managing network sensors.

**FIG. 18** is a flow chart depicting a site survey mechanism using deployed  
25    sensors or Access Points.

**FIG. 19** is a flow chart depicting an alternative adaptive location tracking process.

**DETAILED DESCRIPTION**

30       Exemplary systems and methods are now described in detail. Referring to the drawings, like numbers indicate like parts throughout the views. As used in the

**ATTORNEY DOCKET NO. 093615600016**

description herein, the meaning of “a,” “an,” and “the” includes plural reference unless the context clearly dictates otherwise. Also, as used in the description herein, the meaning of “in” includes “in” and “on” unless the context clearly dictates otherwise. Finally, as used in the description herein, the meanings of “and” and “or” include both  
5 the conjunctive and disjunctive and may be used interchangeably unless the context clearly dictates otherwise; the phrase “exclusive or” may be used to indicate situation where only the disjunctive meaning may apply.

The term “Wi-Fi” is short for wireless fidelity and is another name for IEEE 802.11b. The foregoing discussion of exemplary embodiments may use terminology or  
10 make reference to the IEEE 802.11b standard, or other 802.11 variant; however, those skilled in the art will appreciate that systems and methods may be applied to WLANs meeting these standards as well as WLANs developed according to competing WLAN standards. The term “frame” as used herein shall mean broadly any discretely defined communication transmitted via a computer network and shall not be limited to those  
15 specific frame types (control, management, data and error) defined according to 802.11X standards. As used herein, the term “sensor” or “sensors” as used herein can broadly include wired or wireless sensors, wireless access points and/or combined sensor/access points.

**Architecture of a Typical Environment**

20 FIGs. 2A-E depicts several LAN environments including several configurations of systems and methods disclosed herein. These figures depict a typical LAN environment as depicted in FIG. 1 having wired and wireless components. In contrast to FIG. 1, FIGs. 2A-E include one or more hardware components supporting exemplary environments. The depicted hardware components include a system processor, an SDS  
25 and one or more interfaces to one or more wireless and/or encrypted communications network over which electronic communications are transmitted and received.

The hardware components depicted in these figures are outlined as follows:

- In FIG. 2A, the hardware components include a single device 210A that  
30 includes a local processor serving as the system processor, or at least a portion thereof, and the one or more interfaces to the wireless network. The device 210A is preferably a mobile computer system such as a notebook computer.

**ATTORNEY DOCKET NO. 093615600016**

The local primary and/or secondary storage of device 210A may serve as the SDS; alternatively, portions of the SDS may be provided by other systems capable of communicating with the device 210A such as network addressable data storage 110, local servers 120 and/or wireless stations 170A, 170B. In some configurations, the device's interfaces to the wireless network may be limited to one or more wireless receivers. In others, the interfaces may include one or more wireless transmitters as well as one or more transmitters. If wireless transmitters are included, the device 210 may communicate over LAN 190 using a wireless access point 180A, 180B. In addition, included wireless transmitters may be used to support one or more of the active defense measures described in greater detail below. In some configurations, the device 210A may further include a wired connection (not shown) to Ethernet 150 allowing direct communication between it and systems connected to the wired portion of LAN 190.

- In FIG. 2B, the hardware components include multiple devices 210A, 210B, 210C, 210D. Each device 210A-D includes a local processor and one or more interfaces to the wireless network and is preferably a mobile computer system such as a notebook computer. The individual local processors in the aggregate serve as the system processor. The SDS may include a combination of storage local to each of the devices and/or external storage accessible via the LAN 190. As described above with respect to FIG. 2A, each device includes at least a wireless receiver but may also include additional wireless receivers and/or wireless transmitters. Each device may also include a wired connection (not shown) to Ethernet 150. Finally, the devices 210A-D may further use existing interfaces and/or incorporate additional interfaces to allow peer-to-peer communication among themselves.
- In FIG. 2C, the hardware components include multiple devices 210A, 210B, 210C, 210D, 220. Each device 210A-D may include the various components as described above with respect to FIG. 2B. Device 220 includes a local processor and one or more communication interfaces; this device may be referred to hereinafter as the host system. Device 220's communication interfaces may

**ATTORNEY DOCKET NO. 093615600016**

include only a wired communication interface and may receive data related to wireless communications as forwarded by devices 210A-D over the wire Ethernet 150. In addition to, or instead of, the wired communication interface, device 220 may include a one or more wireless communication interfaces each of which may include a wireless receiver, a wireless transmitter or both. In configurations where devices 210A-D support peer-to-peer communication, device 220 may in some of such participate in the peer-to-peer communication and, in such instances, its communication interfaces would include the appropriate communication interface to support this participation. The system processor functionality in the depicted example may be provided by the host system alone and/or by some combination of the devices 210A-D. The host system may in some implementations provide the SDS for the environment; alternatively, the SDS may be supported by some combination of the local storage among the devices 210A-D, the local storage in the host system and external storage available through LAN 190.

- In FIG. 2D, the hardware components include multiple devices 210A, 210B, 210C, 210D, 220, 230A, 230B. Devices 210A-D, 220 support the same functionality and include the same range of components as provided above with respect to FIG. 2C. In addition, devices 230A, 230B are sensor devices that monitor wireless traffic over the wireless network. These sensor devices at least include a wireless receiver for monitoring the traffic and a communication interface wired (as depicted) or wireless (not shown) allowing communication with one or more of the devices 210A-D and/or the host system 220. In some instances, the sensor devices 230A, 230B may include a wireless transmitter for supporting communication with the other hardware components and/or for supporting various active wireless network defensive measures as discussed below. In some configurations, the sensor device 230A, 230B may further include local processing capability and or local storage capability; in some such, the system processor and/or the SDS may incorporate these local capabilities of the sensor devices 230A, 230B.

**ATTORNEY DOCKET NO. 093615600016**

- In FIG. 2E, the hardware components include multiple devices 220, 230A, 230B. In this configuration, the host system 220 and sensor devices 230A, 230B include the same functionality and range of components as discussed above with respect to FIGs. 2D and 2E respectively. In such configurations, the host system 220 will typically provide a significant portion of the system processor functionality and will only have limited capacity to directly receive wireless network communication. In some of these implementations, the host system 220 may have no wireless communication interface.

The depicted hardware components include a system processor potentially including multiple processing elements, that may be distributed across the depicted hardware components, where each processing element may be supported via Intel-compatible processor platforms preferably using at least one PENTIUM III or CELERON (Intel Corp., Santa Clara, CA) class processor; alternative processors such as UltraSPARC (Sun Microsystems, Palo Alto, CA) could also be used. In some systems, adaptive monitoring functionality, as further described below, may be distributed across multiple processing elements. The term processing element may refer to (1) a process running on a particular piece, or across particular pieces, of hardware, (2) a particular piece of hardware, or either (1) or (2) as the context allows. The sensor devices 230A, 230B depicted in FIGs. 2D-E may in some preferred configurations include more limited optimized local processors such as a digital signal processor (DSP). Other implementations can use in addition, or instead, a general purpose processor, an application specific integrated circuit (ASIC), a field programmable gate arrays (FPGA), multiple such and/or combinations thereof.

The depicted hardware components include an SDS that could include a variety of primary and secondary storage elements. In one configuration, the SDS would include RAM as part of the primary storage; the amount of RAM might range from 64 MB to 4 GB in each individual hardware device although these amounts could vary and represent overlapping use such as where the host system 220 supports additional functionality such as integrated with firewall system 145 for providing unified wired and wireless security. The primary storage may in some implementations include other forms of memory such as cache memory, registers, non-volatile memory (e.g., FLASH,

**ATTORNEY DOCKET NO. 093615600016**

ROM, EPROM, etc.), etc. The sensor devices 230A, 230B depicted in FIGs. 2D-E may in some implementations include more limited amounts and kinds of primary storage. In one such implementation, the primary storage in the sensor devices includes FLASH memory.

5           The SDS may also include secondary storage including single, multiple and/or varied servers and storage elements. For example, the SDS may use internal storage devices connected to the system processor. In implementations where a single processing element supports all of the security analysis functionality, such as seen in FIGs. 2A and 2E, a local hard disk drive may serve as the secondary storage of the  
10       SDS, and a disk operating system executing on such a single processing element may act as a data server receiving and servicing data requests.

          It will be understood by those skilled in the art that the different information used in the security enhancement processes and systems may be logically or physically segregated within a single device serving as secondary storage for the SDS; multiple  
15       related data stores accessible through a unified management system, which together serve as the SDS; or multiple independent data stores individually accessible through disparate management systems, which may in some environments be collectively viewed as the SDS. The various storage elements that comprise the physical architecture of the SDS may be centrally located, or distributed across a variety of  
20       diverse locations.

          The architecture of the secondary storage of the system data store may vary significantly in different implementations. In several such, database(s) are used to store and manipulate the data; in some such implementations, one or more relational database management systems, such as DB2 (IBM, White Plains, NY), SQL Server  
25       (Microsoft, Redmond, WA), ACCESS (Microsoft, Redmond, WA), ORACLE 8i (Oracle Corp., Redwood Shores, CA), Ingres (Computer Associates, Islandia, NY), MySQL (MySQL AB, Sweden) or Adaptive Server Enterprise (Sybase Inc., Emeryville, CA), may be used in connection with a variety of storage devices/file servers that may include one or more standard magnetic and/or optical disk drives using  
30       any appropriate interface including, without limitation, IDE and SCSI. In some environments, a tape library such as Exabyte X80 (Exabyte Corporation, Boulder, CO),

**ATTORNEY DOCKET NO. 093615600016**

a storage attached network (SAN) solution such as available from (EMC, Inc., Hopkinton, MA), a network attached storage (NAS) solution such as a NetApp Filer 740 (Network Appliances, Sunnyvale, CA), or combinations thereof may be used. In others, the data store may use database systems with other architectures such as object-oriented, spatial, object-relational or hierarchical.

Instead of, or in addition to, those organization approaches discussed above, certain environments may use other storage implementations such as hash tables or flat files or combinations of such architectures. Such alternative approaches may use data servers other than database management systems such as a hash table look-up server, procedure and/or process and/or a flat file retrieval server, procedure and/or process. Further, the SDS may use a combination of any of such approaches in organizing its secondary storage architecture.

The hardware components may each have an appropriate operating system such as WINDOWS/NT, WINDOWS 2000 or WINDOWS/XP Server (Microsoft, Redmond, WA), Solaris (Sun Microsystems, Palo Alto, CA), or LINUX (or other UNIX variant). In one implementation, the devices 210A-D and/or host system 220 include a LINUX (or other UNIX variant) operating system; although others may include a WINDOWS/XP (or other WINDOWS family) operating system.

Depending upon the hardware/operating system platform of the overall environment, appropriate server software may be included to support the desired access for the purpose of configuration, monitoring and/or reporting. Web server functionality may be provided via an Internet Information Server (Microsoft, Redmond, WA), an Apache HTTP Server (Apache Software Foundation, Forest Hill, MD), an iPlanet Web Server (iPlanet E-Commerce Solutions - A Sun - Netscape Alliance, Mountain View, CA) or other suitable Web server platform. The e-mail services may be supported via an Exchange Server (Microsoft, Redmond, WA), sendmail or other suitable e-mail server. Some environments may include one or more automated voice response (AVR) systems that are in addition to, or instead of, the aforementioned access servers. Such an AVR system could support a purely voice/telephone driven interface to the environment with hard copy output delivered electronically to suitable hard copy output

**ATTORNEY DOCKET NO. 093615600016**

device (e.g., printer, facsimile, etc.), and forward as necessary through regular mail, courier, inter-office mail, facsimile or other suitable forwarding approach.

Some configurations include sensor devices 230A, 230B of a form such as depicted in FIGs. 7A-C. FIG. 7A depicts a sensing device having combined  
5 functionality of an access point and sensor. The device includes a transceiver antenna 705 and a sensing antenna 710. The transceiver antenna 705 allows receipt and transmission of wireless signals according to a predetermined protocol such as a variant of IEEE 802.11. Wireless stations associate with the active radio (transceiver antenna) which connects through port 720 to a wired network such as a network interface to a  
10 local Ethernet and/or to a further wireless network (transceiver not shown), a modem allowing connection to a network or direct connection to a host system or peer system or combinations thereof. The sensing antenna 710 allows reception of wireless signals according to the protocol without impacting performance of transceiver. The sensing antenna 710 receives all wireless signals in parallel with the transceiver antenna 705.  
15 The sensor can further include local data storage 715 that serves as the SDS, or a portion thereof. This local storage 715 contains any necessary operating code and/or data such as accumulated security data, network configuration data, sensor identification information and/or network communication related data. This local storage typically include DRAM, FLASH memory or combinations thereof. The  
20 sensor can further include a local processor 725 that serves as the system processor, or a portion thereof. This local processor 725 supports communication management and security collection, and in some implementations security analysis, functionality. The local processor can be any microprocessor, ASIC, DSP, FPGA or combination thereof that has the computing power capable of managing the two wireless components 705  
25 and 710 and the auxiliary components of the device (e.g., local storage 715, network interface 720, etc.); for example, a Pentium Class microprocessor (Intel) or faster is capable of managing the computing needs. The device will also include a connection to a power source such as depicted alternating current (AC) interface 730 although other embodiments could in addition, or instead, include a power over Ethernet  
30 compatible interface or a repository for one or more disposable and/or rechargeable batteries.

**ATTORNEY DOCKET NO. 093615600016**

In a network with a multitude of sensing agents, dynamic sensor discovery can be used to create primary and secondary sensing devices and clustered data forwarding. This can lead to several advantages, including optimized sensing uptime, minimized monitoring redundancy, and distributed processing workload. An agent will collect  
5 data from one or more sensors, and either create a local representation of such data in a local data store, send it directly to a remote data store or perform both operations. Sensor election will select, from a number of sensors in a given area, a primary and one or more secondary or backup sensors. This election can be based on a number of factors, including without limitation coverage area, functional capability and/or  
10 numerical priority based on device address.

Multiple sensing agents can be used in some environments to collect data within or from a single sensor or across multiple sensors. FIG. 17 depicts a dynamic sensor discovery process in a network with a multitude of sensing agents. A plurality of wireless network sensors in a network region are identified. In step 1700, configuration  
15 information associated with a wireless network is read from a configuration file. In some instances, this step need not occur; in some such instances, configuration information is not required or can be determined implicitly or dynamically.

In step 1705, wireless network sensors within a given region are identified. In some implementations, a broadcast announcement message is sent via either the wired  
20 or wireless network interface to a set of sensors potentially within the region. Sensors monitor particular logical network ports to recognize and process such messages. Each of the identified sensors within a region is designated as either a primary or secondary (backup) sensor for the region, step 1710. This election can be based on coverage area, functional capability and/or numerical priority based on device address. In some  
25 implementations, the designation is communicated to each sensor, and the receiving sensor may alter configuration and monitoring parameters based upon the designation. A collection point is selected, step 1715. A communication indicating the determined collection agent is transmitted to the wireless sensors in the network region. The collection agent collects data from the one or more identified sensors. The collection  
30 agent can create a local representation of such data in a local datastore, sends it directly to a remote datastore or performs both operations, step 1720.

**ATTORNEY DOCKET NO. 093615600016**

In the some instances, such as depicted, one or more of the wireless sensors, typically at least the one designated as primary, are monitored for status changes in step 1725. Upon a detection of a status change at one or more of the identified sensors can trigger a particular event. Such an event can include one or more of forwarding of  
5 collected data from the collection agent, collecting data from the sensor(s) with a change in status, step 1720 or reconfiguring by performing sensor discovery again, step 1705.

The above process in some environments can be repeated for a number of network regions. In addition, or instead, the process can be repeated a number of times  
10 for the same network region. The repetition can occur periodically or aperiodically. For aperiodic repetition, the repetition can result from occurrence of an event or upon request.

FIG. 7B depicts a stand-alone sensor system. In this system, a wireless transceiver for supporting access point functionality is not included. The description  
15 above with respect to FIG. 7A provides description of the like numbered components in FIG. 7B. This system includes a further communication interface 735. This additional interface can be used to connect further devices such as a standard access point. This would be useful for installing a sensor at a location with an existing access point without having to run another network line. Any data sent outbound from the device  
20 connected to interface 735 would be forwarded via network interface 720. Any data received at network interface 720 directed to the device would be forwarded via interface 735.

FIG. 7C depicts a modified access point system. In this system, a separate antenna is not provided for parallel monitoring of wireless signals. Instead, wireless  
25 transceiver 705 is responsible for both access point and signal monitor functionality. This functionality can be implemented in software or hardware of the local processor 725, or as a modified logic within the transceiver itself. This system has the advantage that existing access points with sufficient local processing capability can be modified through either a hardware addition or a software upgrade to support the monitoring  
30 capability. One disadvantage is that the original access point may not have been

**ATTORNEY DOCKET NO. 093615600016**

intended to support both functionality and, therefore, access point functionality may be degraded in some instances.

As previously described, the sensors 230A-B and/or devices 210A-D in some configurations collect and forward security related data to a host system 220 for further  
5 processing and analysis. Some such environments provide for local processing of security data. FIGs. 8A-B are flow charts depicting an exemplary security data collection process. In some implementations, this process can be executed by sensors 230A-B and/or devices 210A-D.

In some particular environments using an 802.11 compatible network, the  
10 hardware sensors read 802.11 radio waves and strip management and control frames, aggregate statistics and send collected information to a backend server. A hardware sensor can have several configurations. Three such as depicted in FIGs. 7A-7C would be a stand-alone hardware sensor (FIG. 7B), a combination 802.11 Access Point/hardware sensor (FIG. 7A), and a modified 802.11 Access Point capable of  
15 stripping management and control frames and sending them back to a central server for analysis (FIG. 7C).

A hardware sensor will typically include at least one 802.11 radio capable of reading 802.11 radio waves. To provide functionality for securing a wireless network, the hardware sensor strips 802.11 management and control frames off of wireless data  
20 transmissions and sends real-time or batched data back to a centralized server (*e.g.*, host system 220) for analysis and processing to determine intrusions or other network activity such as health or performance monitoring or performing such analysis and processing locally in peer-to-peer configurations.

In the three above mentioned configurations, the stand-alone hardware sensor  
25 would have an 802.11 radio operating in “promiscuous mode” in order to be undetectable from the airwaves and still read all 802.11 network traffic. In operating in promiscuous mode, the hardware sensor would not be able to transmit data such as beacon management and would be in a read-only operation mode. The sensor software embedded on the device would read 802.11 frames from the wireless network and  
30 interrogate them to strip the management and control frames from the data frames,

**ATTORNEY DOCKET NO. 093615600016**

collect the data and send it to the back-end server. The process to collect the data in one preferred approach is as follows:

5 The physical hardware powers up and loads the operating system (preferred OS: Real-Time Linux or RTOS) to an operational state, step 800. The first-time execution of the sensor process after power up (step 805), a timer is initialized for management and control frames buffering (step 810). The timer allows the management and control frames to be buffered until the timer reaches a predetermined elapsed time, at which point they will be forwarded to a server or peer for processing or processed locally. Although other implementations can forward unbuffered management and control  
10 frames and would therefore not require a timer, or any process steps involving the timer.

A wireless packet frame is then read from the wireless network, step 820. Frames are read so that the frame content can be interrogated in down-stream processes. This is also the entry point 815 in the process for retrieving the next frame  
15 after interrogation of the present frame.

The packet frame read off the wireless network is interrogated to determine if the frame is of a redundant type such as management or control frames, step 825. If the frame is of a redundant type, processing continues at entry point 830 in FIG. 8B. Management and control frames are broadcast more frequently than data frames and are  
20 protocol specific. Further interrogation of a management or control frame is performed to determine whether the frame is a redundant type frame (*i.e.*, Beacon Frame), step 855. If not, control passes back to entry point 815 in FIG. 8A. Management and control frames such as beacon frames are broadcast more frequently than data frames and can be buffered as one record with a frame count and to reduce the traffic on the  
25 network as frames are transmitted to the server or to a peer or to reduce overhead of local processing. The buffering can be accomplished by maintaining a frame count for the particular type of redundant frame (step 860) and populating an appropriate data structure based upon the redundant frame type (step 865). If an appropriate time interval has elapsed or if a particular time has been reached (step 870), or if no  
30 buffering is intended, processing proceeds to entry point 845 in FIG. 8A for forwarding of the redundant frame information to the central server or peer or for local processing

**ATTORNEY DOCKET NO. 093615600016**

depending upon the particular system. If the timer does not trigger transmission or processing, processing continues at entry point 815 for retrieval of the next frame in FIG. 8A.

5 If the frame is not of a redundant type, processing continues at step 835 where the header data is stripped from the wireless packet frame. The header data is used to get origin/destination data as well as for maintaining state.

10 In step 840, a data structure is populated with pertinent information concerning wireless station state and protocol activity as well as origin and destination information for later down-line processing by a backend analysis server, by a peer or a local processor.

Once data is accumulated and preprocessed by the remote sensor, the resulting data structures are passed back to the central server or a peer over IP or locally processed for intrusion detection analysis (step 850). The process continues at entry point 815 with the retrieval of the next frame.

15 The device that is a combination hardware sensor and access point, one 802.11 radio would operate as a normal 802.11 access point operating in infrastructure mode that would allow wireless stations to associate and pass data through to the wired network. The additional 802.11 radio would operate in promiscuous mode just as a stand-alone hardware sensor would operate. This would give the device the ability to  
20 send and receive data as a normal 802.11 access point while utilizing the additional radio to monitor the airwaves against intrusions and monitor the wireless network for performance and health monitoring.

The device that is an access point modified to provide monitoring capability would utilize a single 802.11 radio to send and receive data with wireless stations but  
25 would utilize an SNMP mechanism to send traps back to a back end server when events occur such as intrusions or attacks against the access point. This method is not as effective as the previously mentioned devices but can provide additional information that is not collected by standard operating access points.

30 In one environment, devices 210A-D and host system 220 can be configured locally or remotely, and configuration can occur through an interactive interface and/or through a command line interface. The interactive interface is accessible locally

**ATTORNEY DOCKET NO. 093615600016**

whereas the command line interface is accessible either locally or remotely. Remote access is preferably granted through the use of a secure shell (SSH) client communicating with an SSH server running on the device or host system.

5 In some applications, remote monitoring of wireless nodes can be constrained by the available network capacity linking the remote sensor to one or more collection agents and/or centralized management and monitoring applications. To allow operation in such environments, adaptive network bandwidth control can provide an ability to dynamically decrease or increase the use of bandwidth while preserving monitoring fidelity across the population of detectable wireless devices. Bandwidth control may be  
10 implemented either via static rate configuration that is used to specify an upper bound on utilized network bandwidth, via dynamic determination based upon historical data and/or configuration information or via network signaling that may be used to alter the utilized bandwidth dynamically over time. In either case, the maximum available bandwidth is used to control not only the rate of traffic but also the sampling of the  
15 wireless network activity.

FIG. 15 depicts an exemplary process where a remote sensor is linked to a centralized management and monitoring application to allow remote monitoring of wireless nodes in environments constrained by the available network capacity. Network traffic is scanned in step 1500. A determination is made as to whether the  
20 bandwidth limit has been reached in step 1505. If the bandwidth limit is not met, the frame can be transferred to a monitoring application in step 1503.

If the limit has been met, buffering and/or filtering of the scanned network traffic occurs and transferred to the monitoring application at a more metered rate. In step 1510, frames are buffered into a local data store within the remote sensor. As long  
25 as there is sufficient buffering to absorb traffic bursts that exceed the targeted maximum bandwidth utilization, no captured or incoming data has to be discarded. In the case, however, where such buffering is insufficient, downsampling of the data stream can occur to meet the target bandwidth constraint. To do this, network traffic is sampled in such a manner to preserve samples across each of the monitored wireless  
30 devices in step 1515. This can be done via weighted round-robin servicing of each unique device, as identified via its MAC address. In addition to, or instead of,

**ATTORNEY DOCKET NO. 093615600016**

downsampling, low priority information can be discarded first. For example, redundant data, low threat data, data from a sensor more often sampled than others and/or network control frame data can be discarded in a prioritize, or unprioritized manner. In addition, or instead, data can be aggregated with previously buffered data where  
5 feasible. The frames are sent in conformance with the target rate in step 1520 and then network scanning continues in step 1500.

*Wireless Network Topology Mapping and Visualization*

Management of a wireless network differs in many ways from the management of a wired network. One important difference is the more dynamic nature of nodes  
10 (computers, PDAs, 802.11 cell phones, etc) in the network. In a wired network, connections to the network occur only at fixed locations. In a wireless network, nodes are not tied to physical connectivity to the network; a wireless network has no traditional boundaries and its topology can change at a fairly high rate.

This dynamic change is due to the ability of wireless network users to roam  
15 across multiple networks as well as the ability of modern wireless protocols to support instantaneous creation of ad hoc networks. Additionally, due to the nature of wireless RF transmission, connectivity may vary much more dynamically than in a wired network. This is due to physical channel variations such as noise, multipath, transmission obstacles, etc. that are not typically a factor in wired networks. Given  
20 these features, the connectivity patterns and network topology can change from moment to moment.

FIG. 9 depicts a process that supports the capture, and in some cases visualization, of a wireless network topology over time. This mechanism utilizes the stateful analysis capabilities of the network behavior engine to capture and track the  
25 connectivity patterns of users and the networks that are established over time.

The monitoring process is initialized in step 910. Network data is accumulated over a defined time period (an epoch or interval) by processing network data in step 920 until an epoch is complete as determined in step 930. This epoch may vary in length depending upon the depth of analysis and state accumulation desired. In any  
30 case, at the end of an epoch, statistical and state analysis is performed on the

**ATTORNEY DOCKET NO. 093615600016**

accumulated data in step 940. In step 950, topology data is generated and/or updated from the network data and/or data generated in step 940.

5 This data accumulation process (steps 910-940) can be the same monitoring process as depicted and described herein below with respect to FIG. 4. Initialization in step 910 can include the FIG. 4 configuration process as previously discussed. In such case, topology updating 950 would occur concurrently with, before or after the statics update step 470. In some such processes, the multidimensional IDS process step 435 can include testing for various departures from topology expectations.

10 Step 960, topology analysis may occur automatically after each epoch; alternatively, progression to step 960 may only occur as a result of an on-demand inquiry from a user or another system. In either case, the topology data can be analyzed in several ways.

For analysis purposes, this topology can then be represented mathematically as a graph, with a set of nodes and edges interconnecting the nodes per the observed  
15 pattern. This generated topology can also be further processed to generate a visualization or to compare with a prior network topology to evaluate potential security and/or policy violations. The topology comparison in some instances could include rules-based comparison for potential security and/or policy violations. In addition, or instead, the topology could be subject to a pattern matching-based comparison to  
20 identify a topology state that violates security and/or policy constraints. Any suitable pattern matching approach could be used; in some instances, neural networks, lexical analysis and/or bit masking could be included as part of such pattern matching. Through collection of state information related to activity, usage and connectivity patterns, the topology can be constructed and updated over time as new state  
25 information is collected by the system. Additional information also includes device identity and classification, allowing each node in the network to be represented in terms of its capabilities, its state and its usage patterns. Further, these patterns can also be analyzed via a number of mechanisms including pattern matching to discriminate between normal and anomalous activity.

30 The analyzed topology data is then output in step 970. This topology information can be output as a visualization in some instances through the use of

**ATTORNEY DOCKET NO. 093615600016**

graphical representations with encodings for state, traffic, security; and connectivity. FIGs. 12A, 12A1 and 12B depict an example visualization interface showing a tracked topology. In such cases employing a graphical representation, color of various graphical items can be used to convey additional information regarding the state, traffic, security and connectivity of particular devices represented by the graphical items.

In one particular implementation as depicted in these figures, the colors have prescribed meanings as follows for sensors, access points/bridges and stations:

Sensors: Sensors can be blue, green or red and can have the letters L, S, LL, SS, SL, or LS. L means locked on channel, and S means scanning channels. The single versus double letters is for the two different types of hardware.

- Blue - Default Sensor that is a placeholder for imported/manual added devices that have not been observed yet.
- Green - Sensor is online.
- Red - Sensor is off-line.

Access Points/Bridges: Access Points and bridges can be blue, green, red, or gray.

- Blue: manually added or imported into the system but has not been observed yet
- Green: authorized
- Red: unauthorized
- Gray: ignored

Stations: Wireless stations can be blue, green, red, gray, purple or orange. Stations can also have a W in them if they are on a watch list.

- Blue: manually added or imported into the system but has not been observed yet
- Green: authorized on the access point (could be current state or historical)
- Red: unauthorized on the access point (could be current state or historical)
- Gray: ignored
- Purple: unassociated wireless station

**ATTORNEY DOCKET NO. 093615600016**

- Orange: adhoc station

In addition to, or instead of, a visualization output, an alert could be generated if a topology violation were detected as a result of the analysis. Such a notification could be in the form of a communication to a user and/or another system as described in

5 further detail below with respect to alerts.

To facilitate network performance optimization, calibration and location tracking, an infrastructure-based site survey mechanism can use deployed sensors or access points. These sensors can record wireless network RF signal characteristics per device per location per protocol and frequency band. These signal characteristics can  
10 then be used as calibration information describing the particular network being monitored.

In one implementation, site survey mode can be enabled via either explicit start/stop signaling passed to the sensor or access point or automatically via a prescribed "site-survey" data pattern. In the case of explicit signaling, the site survey  
15 client can perform a handshake with each monitoring sensor or access point, or with a proxy of all such sensors such as a centralized management subsystem that acts as a collection agent for one or more sensors, access points or combined sensor/access points. This handshake can be done in secure or non-secure mode, and can be used to start and stop data collection as well as to provide site survey client identifiers and  
20 calibration data such as position coordinate information. In secure mode, the contact can use encryption technology, authentication technology or combinations thereof. In the case of an automatic calibration, the prescribed pattern can use a defined "START SSID", "END SSID" and "IDLE SSID" to indicate that the client is starting a survey, ending a survey or transitioning between locations on the floor plan being surveyed and  
25 calibrated.

Synchronization of calibration location and RF signal data can be done via explicit exchange of physical coordinate and site survey client ID information as part of the start and stop signaling exchange. This can result in a virtual session that exists for the duration between the start and stop messaging exchange. During this time, data  
30 collected by the sensor(s) and Access Point(s) is tagged by calibration position and contains a vector of RF signal characteristics; such characteristics can include, without

**ATTORNEY DOCKET NO. 093615600016**

limitation, any combination of signal strength, signal-to-noise ratio, and noise level. Client identifiers can be a standard device hardware address, such as the MAC address, sent in combination with a recognized wireless service set ID (SSID).

Coordinate information can also be received. Such information can be encoded  
5 as pixel positions within a loaded bitmap that would typically represent the floor plan being surveyed and calibrated for location tracking. This information may be encoded into the probe requests or uploaded to the system via a post-processing step. The client identifiers are correlated with either encoding of the pixel positions within the probe requests as unique SSID values or through post-processing of the signal strength  
10 database in which the pixel positions and SSID values are uploaded and compared to the recorded SSIDs and signal strength values. This allows a linkage between the wireless survey client probing at pixel position (x,y,z) and the RF signal properties for this position that have been recorded by one or more sensors.

FIG. 18 depicts an infrastructure-based site survey mechanism utilizing  
15 deployed sensors or access points to facilitate network performance optimization. These signal characteristics can then be uploaded to a system data store where they may be used as calibration information describing the particular network being monitored. Alternatively, the characteristics can be processed locally or in a peer-to-peer environment in conjunction with other deployed sensors and/or access points.

20 In step 1800, configuration information associated with a wireless network and/or data collection agents and/or sensors associated therewith is read from a configuration file. In some instances, this step need not occur; in some such instances, configuration information is not required or can be determined implicitly or dynamically.

25 Site survey mode is initiated in step 1805. In some implementations, site survey mode can be enabled via either explicit start/stop signaling passed to the sensor or Access Point or automatically via a prescribed "site-survey" data pattern. In the case of explicit signaling, the site survey client typically performs a handshake with each monitoring sensor and/or Access Point, or with one or more proxies acting as data  
30 collection agents for all such sensors. This handshake can be done in secure or non-

**ATTORNEY DOCKET NO. 093615600016**

secure mode, and can be used to start and stop data collection as well as to provide site survey client identifiers and calibration data such as position coordinate information.

5 Synchronization of calibration location and RF signal data collection is begun in step 1810. In one implementation, this can occur via explicit exchange of physical coordinate and site survey client ID information as part of the start and stop signaling exchange. This results in a virtual session that exists for the duration between the start and stop messaging exchange.

10 Probing begins at step 1815. The sensors are used to record wireless network RF signal characteristics. In a typical implementation, the process loops through the steps 1815 to 1830 on a per device per location per protocol and frequency band basis. In step 1825, data collected by the sensor(s) or AP(s) is tagged by calibration position and contains a vector of RF signal characteristics. The RF signal characteristics can include a variety of attributes such as one or more of signal strength, signal-to-noise ratio, and noise level. Once probing is stopped in step 1825 for a particular iteration, 15 the process moves to a new coordinate in step 1830, and determines if calibration is finished in step 1835. If a new coordinate is identified requiring probing, the process continues at step 1815 with the probing of the new coordinate.

20 Upon completion of calibration as determined at step 1835, the survey data is stored. Typically, the data can be uploaded to a database and stored based upon the client identifiers, the received coordinate information, the received RF signal characteristic data or combinations thereof in step 1840. The data is stored in the SDS. The portion of the SDS can be either local to the device performing the calibration such as a centralized management system, remote in a centralized data archive or distributed across surveyed clients or proxies.

25 The entire process can, in some implementations, be performed on a periodic or aperiodic basis. The periodicity of periodic performance can be according to a predetermined maintenance, reporting and/or analysis schedule. Aperiodic repetition can occur as a result of an external request from a user or other system or upon occurrence of one or more predetermined events.

**ATTORNEY DOCKET NO. 093615600016***Access Point Configuration*

In some implementations, an interactive interface is provided for configuring the access point and various hardware components and supplying a variety of configuration data including thresholds values of various kinds. In one such

- 5 implementation, an administration program area provides such an interface and allows:
- definition and configuration of access point settings and policies;
  - definition of authorized user identities and authorized types or modes of behavior
  - creation and/or designation of thresholds used to trigger
  - 10 intrusion/detection alarms for authorized access points;
  - creation and/or designation of default thresholds used to trigger intrusion/detection alarms for non-authorized access points; and
  - configuration of settings for the various hardware/software components.

The administration program area, in some environments, offers standard

15 windowing interface featuring tabbed pages for easy navigation between configuration functions. From within each of the tabbed pages, an *Edit* button allows modification of the values. After editing the data, *Accept* temporarily saves the changes. *Commit* permanently saves and applies edits (until edited again). Accepted changes persist until the system is restarted whereas committed changes persist until across restarts.

20 One particular implementation automatically attempts to detect and record all the configured properties for all access points it observes. The settings constitute access point "policies"--when access point properties deviate from those recorded, one or more alarms can be generated. The values for an access point can be modified manually to alter the generation of specific alarms. Policies for off-line access points

25 can also be created in some implementations using an *Add* feature.

The table below provides a summary of several access point properties displayable and/or configurable in some exemplary systems and methods.

Values	Description
Access Point ID	The MAC address of the access point.
Access Point Name	The user-defined name of the access point.

## ATTORNEY DOCKET NO. 093615600016

Values	Description
Extended Service Set ID	The name of the Extended Service Set indicating the wireless network to which the access point belongs.
Access Point Vendor	The manufacturer of the access point. In some cases, this is detected by comparing the first three bytes of its MAC address with a database of OUI numbers.
Supported Rates	The data transfer rates the access point supports. In some cases, this value (or these values) can be edited to specify the supported rates.
Authentication Modes	Whether the access point accepts non-authenticated network connections and/or also accepts shared key authentication. (If connections are detected that deviate from either of these settings, an alarm can be generated.)
Configured to Run WEP	Whether or not the access point is configured to require WEP encryption.
AP Mgmt From Wireless Network	Whether the access point is configured to allow users to directly administer its settings over the wireless network.
Authorized Access Point	Whether this access point is authorized to be present in the air space. Unauthorized access points, when detected, can generate alarms. (In some instances, a change in this value will not take effect until the system is restarted.)

For each access point, a station maintenance screen or menu may allow the specification of the stations that are authorized to use it. One particular exemplary implementation of such a screen or menu, automatically detects all stations within the footprint of the access point's Basic Service Set (BSS) and enters their MAC addresses in an Observed column. Such stations can be indicated as an authorized member of the BSS by selecting them in the Observed column and designating them as Valid. Designated stations are moved to a Valid column. (Stations can, in some instances, be designated as invalid by selecting and marking them in the Valid column.) Stations not auto-detected can be manually entered by specifying its MAC address in a *Enter New*

**ATTORNEY DOCKET NO. 093615600016**

*Station* input field and triggering an *Add Station* feature. Authorization of stations can also be done via file import, access control server export or via direct configuration through a typical access point configuration and management port.

*Access Point Threshold Configuration and Aggregate Station Thresholds*

- 5            Systems and methods can generate alerts if network traffic that exceeds thresholds is detected. In one particular implementation, all detected or manually configured off-line access points are listed in a *Select AP* pick list. Thresholds associated with each access point in the pick list can be edited by selecting the particular access point. Such threshold values can be either temporary (until the next  
10 restart) or persistent across restarts (until a further edit designated as persistent).

Values	Description
Signal Strength Threshold	If the signal strength for any station in the BSS is lower than this value, an alarm can be generated.
# of Associations per Minute	Enter the maximum number of associations per minute to allow with all stations combined. (Preferably, this value is not higher than twice the number of stations in the BSS.)
# of Associated Stations	Enter the maximum number of stations allowed to associate at any one time with this access point. The number should reflect the actual number of stations. If a greater number is detected, an alarm can be generated.

- The following table outlines a set of thresholds used in one particular implementation that refer to the network characteristics encompassing all stations and traffic in the BSS. Special care should be taken when creating the "byte thresholds" that immediately follow. Several factors govern the values entered for each:
- 15            • The "transmission rate" of the access point--how much data it can transmit--is the first consideration. If the transmission rate is only 1 megabyte per second, the thresholds will be much lower than if the transmission rate is 11 megabytes per second.
- 20            • All four "directions" of traffic (wired to wired, wired to wireless, wireless to wired, and wireless to wireless) must add up to less than 100% of available

**ATTORNEY DOCKET NO. 093615600016**

bandwidth. Many administrators will set the individual thresholds such that their combined value is less than 80% of available bandwidth.

<b>Value</b>	<b>Description</b>
# Bytes into BSS from Wired Net	Enter the maximum number of bytes of data per minute allowed into the BSS from the wired portion of your network. If a greater number is detected, an alarm can be generated.
# Bytes from BSS to Wired Net	Enter the maximum number of bytes of data per minute allowed out of the BSS to a wired portion of your network. If a greater number is detected, an alarm can be generated.
# Bytes between Stations in BSS	Enter the maximum number of bytes of data per minute allowed to be transmitted within the BSS from all stations. If a greater number is detected, an alarm can be generated.
# Bytes from Wired Net to Wired Net	Enter the maximum number of bytes of data per minute allowed to be transmitted from a wired portion of the network to another wired portion of the network, using the access point as a bridge. If a greater number is detected, an alarm can be generated.
Total Data Frames Seen	Enter the maximum number of data frames per minute from all stations combined allowed to be transmitted. If a greater number is detected, an alarm can be generated.
Total Mgmt Frames Seen	Enter the maximum number of management frames per minute from all stations combined allowed to be transmitted. If a greater number is detected, an alarm can be generated.
Total Ctrl Frames Seen	Enter the maximum number of control frames per minute from all stations combined allowed to be transmitted. If a greater number is detected, an alarm can be generated.
Total Ad hoc Frames Seen	Enter the maximum number of ad hoc frames per minute from all stations combined allowed to be transmitted. If a greater number is detected, an alarm can be generated.

**ATTORNEY DOCKET NO. 093615600016***Individual Station Thresholds*

The following table outlines a set of potential thresholds applied to any individual station in one particular implementation. If any single station reaches one of these thresholds, an alarm can be generated.

5

<b>Column</b>	<b>Description</b>
Signal Strength Threshold	If the signal strength for any station in the BSS is lower than this value, an alarm can be generated.
# of Associations per Minute	Enter the maximum number of associations per minute any station is allowed to make with an access point. If a greater number is detected, an alarm can be generated.
# of Bytes Transmitted	Enter the maximum number of bytes of data per minute any station is allowed transmit. If a greater number is detected, an alarm can be generated.
# of Bytes Received	Enter the maximum number of bytes of data per minute any station is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Data Frames Transmitted	Enter the maximum number of data frames per minute any station is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Data Frames Received	Enter the maximum number of data frames per minute any station is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Transmitted	Enter the maximum number of management frames per minute any station is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Received	Enter the maximum number of management frames per minute any station is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames	Enter the maximum number of control frames per minute any

**ATTORNEY DOCKET NO. 093615600016**

<b>Column</b>	<b>Description</b>
Transmitted	station is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames Received	Enter the maximum number of control frames per minute any station is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Fragment Frames Seen	Enter the maximum number of fragment frames per minute from any station that are allowed. If a greater number is detected, an alarm can be generated.
# of Decrypt Error Frames Seen	Enter the maximum number of decrypt error frames per minute from any station that are allowed. If a greater number is detected, an alarm can be generated.

*Access Point Station Thresholds*

The following table outlines a set of thresholds, in one particular implementation, applied to the access point itself, and will typically be somewhat more than the Aggregate Station thresholds.

5

<b>Column</b>	<b>Description</b>
Signal Strength Threshold	If the signal strength for any frame is lower than this value, an alarm can be generated.
# of Associations per Minute	Whereas stations must associate with an access point, access points do not associate with themselves. Therefore, this value should be zero, indicating that it does not associate.
# of Bytes Transmitted	Enter the maximum number of bytes of data per minute this access point is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Bytes Received	Enter the maximum number of bytes of data per minute this access point is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Data Frames	Enter the maximum number of data frames per minute this access

**ATTORNEY DOCKET NO. 093615600016**

<b>Column</b>	<b>Description</b>
Transmitted	point is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Data Frames Received	Enter the maximum number of data frames per minute this access point is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Transmitted	Enter the maximum number of management frames per minute this access point is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Received	Enter the maximum number of management frames per minute this access point is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames Transmitted	Enter the maximum number of control frames per minute this access point is allowed to transmit. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames Received	Enter the maximum number of control frames per minute this access point is allowed to receive. If a greater number is detected, an alarm can be generated.
# of Fragment Frames Seen	Enter the maximum number of fragment frames per minute this access point can see before generating an alarm.
# of Decrypt Error Frames Seen	Enter the maximum number of decrypt error frames per minute this access point can see before generating an alarm.

*Default Threshold Information*

In one particular implementation, whenever a new access point is detected or manually entered, the specified default settings are applied until it is manually customized. It is assumed that new or unauthorized access points are potential hackers, so it is preferable to set the default thresholds fairly low.

*Aggregate Station Thresholds*

The table below outlines a set of thresholds that refer to the combined statistics for all stations in one particular implementation.

**ATTORNEY DOCKET NO. 093615600016**

<b>Column</b>	<b>Description</b>
Signal Strength Threshold	If the signal strength for any station in the BSS associated with an unknown access point is lower than this value, an alarm can be generated.
# of Associations per Minute	Whereas stations must associate with an access point, access points do not associate with themselves. Therefore, this value should be zero, indicating that it does not associate.
# of Associated Stations	Enter the maximum number of stations allowed to associate with unknown access points. The number should reflect your actual stations. If a greater number is detected, an alarm can be generated.
# Bytes into BSS from Wired Net	Enter the maximum number of bytes of data per minute allowed into the BSS through unknown access points from the wired portion of your network. If a greater number is detected, an alarm can be generated.
# Bytes from BSS to Wired Net	Enter the maximum number of bytes of data per minute allowed out of the BSS through unknown access points to a wired portion of your network. If a greater number is detected, an alarm can be generated.
# Bytes between Stations in BSS	Enter the maximum number of bytes of data per minute allowed to be transmitted within the BSS from all stations through unknown access points. If a greater number is detected, an alarm can be generated.
# Bytes from Wired Net to Wired Net	Enter the maximum number of bytes of data per minute allowed to be transmitted through unknown access points from a wired portion of the network to another wired portion of the network, using the access point as a bridge. If a greater number is detected, an alarm can be generated.
Total Data Frames Seen	Enter the maximum number of data frames per minute for all stations combined allowed to be transmitted through unknown access points. If a greater number is detected, an alarm can be generated.
Total Mgmt Frames Seen	Enter the maximum number of management frames per minute for all stations combined allowed to be transmitted through unknown access

**ATTORNEY DOCKET NO. 093615600016**

<b>Column</b>	<b>Description</b>
	points. If a greater number is detected, an alarm can be generated.
Total Ctrl Frames Seen	Enter the maximum number of control frames per minute for all stations combined allowed to be transmitted through unknown access points. If a greater number is detected, an alarm can be generated.
Total Ad hoc Frames Seen	Enter the maximum number of ad hoc frames per minute for all stations combined allowed to be transmitted through unknown access points. If a greater number is detected, an alarm can be generated.

*Individual Station Thresholds*

The set of thresholds outlined in the table below apply to any individual station in one particular implementation, and will typically be lower than the Aggregate Station thresholds.

<b>Column</b>	<b>Description</b>
Signal Strength Threshold	If the signal strength for any station associated with an unknown access point is lower than this value, an alarm can be generated.
# of Associations per Minute	Enter the maximum number of associations per minute any station is allowed to make with an unknown access point. If a greater number is detected, an alarm can be generated.
# of Bytes Transmitted	Enter the maximum number of bytes of data per minute any station is allowed transmit through unknown access points. If a greater number is detected, an alarm can be generated.
# of Bytes Received	Enter the maximum number of bytes of data per minute any station is allowed to receive through unknown access points. If a greater number is detected, an alarm can be generated.
# of Data Frames Transmitted	Enter the maximum number of data frames per minute any station is allowed to transmit through unknown access points. If a greater number is detected, an alarm can be generated.
# of Data Frames Received	Enter the maximum number of data frames per minute any station is allowed to receive through unknown access points. If a greater

Column	Description
	higher than twice the number of stations in your BSS.)
# of Bytes Transmitted	Enter the maximum number of bytes of data per minute allowed to be transmitted from any access point. If a greater number is detected, an alarm can be generated.
# of Bytes Received	Enter the maximum number of bytes of data per minute allowed to be received by any access point. If a greater number is detected, an alarm can be generated.
# of Data Frames Transmitted	Enter the maximum number of data frames per minute allowed to be transmitted by any Access point. If a greater number is detected, an alarm can be generated.
# of Data Frames Received	Enter the maximum number of data frames per minute allowed to be received by any access point. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Transmitted	Enter the maximum number of management frames per minute allowed to be transmitted by any access point. If a greater number is detected, an alarm can be generated.
# of Mgmt Frames Received	Enter the maximum number of management frames per minute allowed to be received by any access point. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames Transmitted	Enter the maximum number of control frames per minute allowed to be transmitted by any access point. If a greater number is detected, an alarm can be generated.
# of Ctrl Frames Received	Enter the maximum number of control frames per minute allowed to be received by any access point. If a greater number is detected, an alarm can be generated.
# of Fragment Frames Seen	Enter the maximum number of fragment frames per minute allowed for any access point. If a greater number is detected, an alarm can be generated.
# of Decrypt Error	Enter the maximum number of decrypt error frames per minute

**ATTORNEY DOCKET NO. 093615600016**

<b>Column</b>	<b>Description</b>
Frames Seen	allowed for any access point. If a greater number is detected, an alarm can be generated.

Some environments may allow for self-configuration of some or all of the thresholds discussed above. Such self-configuration could occur through a learning mode in which the systems and methods can monitor traffic on the wireless computer network for the first several hours or days after installation. In such a learning mode, alarm notifications can be disabled. It is expected that, in the beginning, the generation of alarms will be very high--hundreds or thousands per day depending on actual network traffic--until thresholds in accordance with the network's normal activity are determined. Once an accurate picture of normal network traffic has been captured, and thresholds are reflective of normal activity, a switch to normal operations mode enables alarm notifications.

In one particular implementation, a command line interface is provided to configure settings that are not available within the graphical user interface. For example, the IP address of a hardware component can be changed, its system clock reset or set to "sync" with a network time server. In other implementations, the graphical user interface and/or the command line interface can allow significant overlap of configuration capability. Further, some implementations have only one or the other interface type. Finally, some implementations provide no interactive interface for configuration and are limited to reading configuration data from a file, deriving configuration data from past monitoring of the wireless computer network or otherwise receiving this data. The command line interface in one particular implementation can be accessed either on the hardware component such as through a command shell such as the Linux Gnome Terminal or over the network using an SSH (preferably, version 2) client.

In one particular implementation, a command shell automatically opens on the hardware component after booting. A terminal icon can appear on the task bar at the bottom of the display; clicking the icon opens additional terminal windows. At the command line prompt, a command is entered to launch the command line interface.

**ATTORNEY DOCKET NO. 093615600016**

An SSH client is launched and connected to the hardware component's IP address. The identity of the user making the connection is verified. At the command line prompt, enter the following command to launch the command line interface:

*Command Line Interface*

5 In one particular implementation, the screen displays in the terminal window provide five "program areas":

- Network--offering options to change IP address, DNS servers, hostname, domain name, mail server, ARP, and create "allow" and "deny" lists.
- Date--allowing time and date editing, time zone setting, and configuration of  
10 an NTP server.
- Service--providing tools to fine-tune the hardware component parameters, configure data management, and reboot and shut down the component.
- Users--allowing creation, editing, and deletion of user accounts allowed access to the graphical user interface.
- 15 • Help--tips on using the application, and detailed help topics.

*Network*

Opening the network settings program area, the following commands are available in one particular implementation:

Command	Description
IP	<p>IP address config</p> <p>Allows modification of the IP address, Subnet mask, and default gateway for the hardware component logged onto.</p> <p>The "IP configuration" screen opens, displaying the current network configuration and allows modification.</p>
DNS	<p>Define DNS servers</p> <p>Adding or deleting a DNS nameserver.</p> <p>The "Nameserver screen" opens, displaying your current DNS server's IP address and allows addition, deletion and modification.</p> <p>Note: Multiple DNS servers can in some cases have an "order" for</p>

**ATTORNEY DOCKET NO. 093615600016**

<b>Command</b>	<b>Description</b>
	processing DNS requests. The first server on the list (identified by the numeral 1) is the first to offer name resolution; the second server on the list (identified by the numeral 2) is the second to process the request if the first is unable to do so. In order to change the order preference of multiple servers, all must be deleted and re-entered in the desired order for them to process DNS requests.
HNAME	<p>Set hostname</p> <p>Changing the name of the hardware component. The Hostname screen displays your current hostname and allows modification.</p> <p>Bear in mind that whenever the hostname is changed, its name must also be modified in all devices that refer to it (e.g., DNS servers).</p>
DNAME	<p>Set domain name</p> <p>Changing the domain to which the hardware component belongs. The Domain name screen displays your current domain name and allows modification.</p> <p>Bear in mind that whenever the domain name is changed, it must also be modified in all devices that refer to it (e.g., DNS servers).</p>
MRELAY	<p>Config mail relay host</p> <p>Configuring a hardware component to send alarms by email. The Mail relay host screen appears and allows entry of qualified hostnames.</p> <p>In one particular environment, mail relay hosts may be referred to by IP address or fully qualified hostname (e.g., myhostname.mydomainname.com) of a mail server to process email alarm messages.</p> <p>Note: the mail server must be configured to allow this appliance to relay email through it, or at least to direct its mail to another mail server that will relay it.</p>
ARP	<p>Config permanent ARP table</p> <p>Creating a permanent ARP table. The ARP table screen displays your</p>

**ATTORNEY DOCKET NO. 093615600016**

<b>Command</b>	<b>Description</b>
	<p>current ARP records and allows modification.</p> <p>In order to protect connections between this hardware component and remote administrators from being hijacked by man-in-the-middle ARP "blasts" (that redirect traffic for this IP address to an alternate MAC address), it is preferable to create permanent ARP records for gateways and other important machines.</p>
<b>HALLOW</b>	<p>Configure /etc/hosts.allow file</p> <p>Specifying which machines are allowed to connect to the hardware component. The Allow list screen displays your current list of allowed machines and allows modification.</p> <p>Machines allowed to connect to this hardware components can be specified. Only those whose IP address, subnet, fully qualified hostname, or domain name match an entry in this list are allowed to connect to this hardware component to run the available administrative programs and routines.</p>
<b>HDENY</b>	<p>Config /etc/host.deny file</p> <p>Identifying machines that may not connect to the hardware component. The Deny list screen displays your current list of denied machines and allows modification.</p> <p>Machines not allowed to connect to this hardware component can be specified. Anyone whose IP address, subnet, fully qualified hostname, or domain name matches an entry in this list are not allowed to connect to this hardware component</p> <p>Note: HALLOW, in one particular implementation, takes precedence over HDENY. For example, if 123.456.789.963 is on the allow list, yet the subnet 123.456.789. is on the deny list, the individual machine above is allowed to connect to the appliance.</p>

*Date*

Opening the date settings program area, the following commands are available in one particular implementation:

**ATTORNEY DOCKET NO. 093615600016**

<b>Command</b>	<b>Description</b>
TIME	Time/Date config Allows configuration of the time/date for the hardware component.
TZ	Set time zone Allows configuration of the time zone for the hardware component.
NTP	Enable/disable NTP Allows configuration of the hardware component to use a network time server.

Note: If you change the system time because, for example, you move the appliance's location from the east to west coast of the United States, you must also locate a new network time server in the same time zone.

**Services**

- 5           Opening the set appliance parameters, configure data management, and restart or shutdown the system area, the following commands are available in one particular implementation:

<b>Command</b>	<b>Description</b>
TUNE	Tune appliance parameters Allows users to modify some of the core values related to the environment's functionality.
DMGT	Data management Allows users to modify how the environment stores its data.
REBOOT	Reboot system Allows graceful restart of the hardware component.
HALT	Halt system Allows graceful shutdown of the hardware component.

**ATTORNEY DOCKET NO. 093615600016***Users*

Opening the Users program area, the following commands are available in one particular implementation:

<b>Command</b>	<b>Description</b>
NEWU	Create user
EDITU	Edit user
DELU	Delete user

The functionality of these features can in one particular implementation match  
 5 with like functionality provided in a standard LINUX user management facility.

Various methods and functions as exhibited in various systems described above and below with respect to adaptive monitoring with bandwidth constraints. In some implementations, one or more processors within architectures of the environments as described above may execute the steps in such methods and provide such functionality.  
 10 The functionality may spread across multiple processing elements. In other cases, any suitable computer readable storage device, media or combination of devices and/or media, including primary storage such as RAM, ROM, cache memory, etc. or secondary storage such as magnetic media including fixed and removable disks and tapes; optical media including fixed and removable disks whether read-only or read-  
 15 write; paper media including punch cards and paper tape; or other secondary storage as would be known to those skilled in the art, may store instruction that upon execution by one or more processors cause the one or more processors to execute the steps in such methods and to provide such functionality.

**Vulnerability Assessment and Threat Identification**

20 Vulnerability assessment is accomplished by analyzing WLAN traffic, and discovering access points and workstations. The system determines how many bytes of data stations are sending and receiving, the mean signal strength for an entire day or the hi/low signal strength for each minute. It can distinguish between network traffic internal to the wireless network and traffic originating from or destined to the physical,  
 25 wired-network and which stations are the largest senders and receivers of data. The system produces broad summaries of data that report high, low, and mean values for a

**ATTORNEY DOCKET NO. 093615600016**

variety of traffic parameters, and detailed views that show minute-by-minute snapshots of your traffic. Traffic parameters include the breakdown of frame traffic (control, management, data, and error frames) and network routing information. The system determines if any traffic has not been encrypted, users are authenticated, and all  
5 hardware is properly configured. The system detects rogue deployments by identifying and locating unauthorized WLANs and ad hoc networks (peer-to-peer networks) that violate company policy and jeopardize security. The system identifies suspicious WLAN traffic across unauthorized channels and frequencies, which can be a common sign of intruders accessing your WLAN or employees abusing their network privileges.

10 The systems and methods according to one particular implementation use an audit of existing wireless hardware and perform a survey the air space surrounding the wireless network prior to activating intrusion detection. In this way, a baseline activity level can be determined.

*Step 1: Hardware Audit*

15 Identify every access point in the wireless computer network. Obtain or determine for each its MAC address, Extended Service Set name, manufacturer, supported transmission rates, authentication modes, and whether or not it is configured to run Wired Equivalent Privacy (WEP) and wireless administrative management. In addition, identify every workstation equipped with a wireless network interface card,  
20 and record the MAC address of each device. Take note of any physical features in the environment (walls, competing electronic devices such as microwave ovens, cordless phones, etc.) that might interfere with wireless signals.

The hardware audit serves as the baseline against which the systems and methods described herein can compare. That is, all access points and wireless stations  
25 should be detected by the various systems and methods described herein. (If an access point or station is not detected, follow logical troubleshooting steps.) On the other hand, it is likely that more devices than expected will be detected. Some of these may be stations or access points not identified or of which no one was aware. Others may be "rogue" devices--surreptitious or unauthorized installations in the network--or  
30 harmless equipment belonging to nearby companies, and others may be actual hackers.

**ATTORNEY DOCKET NO. 093615600016**

Once the systems and methods are in intrusion detection mode, all detected access points and stations can be reported.

*Step 2: Survey Perimeter*

5        Preferably a mobile hardware component is walked around the perimeter of the wireless computer network in a powered up state (allowing it to collect data as it is moved), or placed in a central location for 12 to 24 hours to collect a larger amount of data. A set of one or more distributed sensors could be used instead of, or in addition to, such a mobile hardware component. The benefit of a "walk-around" survey is that it generates a nearly immediate picture of the existing wireless "air space." The benefit of  
10    a "stationary" survey is that over a longer period of time, is greater certainty of detecting devices that only operate intermittently or hackers attempting to penetrate the network off-hours. Repetition of the survey, whether walking or stationary, should occur on all 11 channels.

*Stationary Data Collection*

15        Depending on the size of the wireless network, a hardware component can be placed at the four corners or at intermediate points in the Extended Service Set footprint. At each location, the component should be allowed to passively monitor network traffic for 12-24 hours. Hard copy of network data should be preserved prior to each move.

20    *Walk-around Data Collection*

      Simply walk around the perimeter of the wireless network with the hardware component powered on and open to an overview screen. The various access points and stations within the wireless computer network can be detected. Compare this information with the hardware audit made prior to collecting this data. Repeat this  
25    walk-around survey for each of the eleven channels.

*Step 3: Configure to "Recognize" this Network*

      Each access point detected should be designated as authorized or unauthorized. Each observed station should be designated as valid or not.

**ATTORNEY DOCKET NO. 093615600016**

*Step 4: Place hardware components in discrete locations throughout the wireless network.*

Leave a component in each location from 1-3 days. Each day, print reports to preserve captured information. Based upon this information, specific access point and  
5 station related thresholds can be tuned to distinguish between normal and abnormal traffic patterns.

The intrusion detection system (IDS) engine listens to wireless network traffic. FIG. 3 depicts one preferred process the IDS follows in evaluating data associated with received traffic. In the depicted exemplary process, all packets pass through four  
10 detections systems: signature-based testing, protocol-based testing, anomaly-based testing, and policy deviation-based testing; other implementations may use one or more of these tests, or other tests, in varying combinations.

Initially, configuration information is received in step 305, typically including network default data and risk criteria. This information can be retrieved from a file,  
15 derived or obtained from monitoring the network and/or entered interactively at the outset of the process. The system reads or receives frames from the wireless network in step 310. The received frames are interrogated as follows.

The information within the frame is interrogated to determine if a known attack signature has been identified in step 325. Signatures encode datalink layer attack  
20 patterns as combinations of packet sequences and state. For example, active probing emits a pattern or sequence of network requests. This sequence can be recognized by its packet sequence signature. If the attack signature is identified, the intrusion detection system signals an alarm manager to deliver an alert to the administrator in step 345.

25 If no attack signature is identified, the frame information is passed through a protocol violation engine to determine if the protocol used in the frame is authorized in step 330. Protocol analysis examines whether or not protocol usage is legitimate. For example, emitting a large number of association or disassociation requests in a short interval is not a legitimate use of the protocol. If the protocol used in the frame is  
30 outside of the authorized protocol set, the intrusion detection system signals an alarm manager to deliver an alert to the administrator in step 345.

**ATTORNEY DOCKET NO. 093615600016**

If the protocol test passes, in step 335, the IDS checks the frame data for statistical anomalies against the SDS, or a statistics database maintained therein. Anomaly based detection computes such values as the mean, non-zero mean, standard deviation, autocorrelation and peak for each time slice throughout the day. This can be  
5 used to create a normalized statistics database for each time slice and user. Current activity is then monitored and compared with the recorded statistics vector. If the difference is larger than a configurable threshold, an alert is generated. Instead of, or in addition to, this approach, a Bayes test can be applied to deduce the probability that the current statistics vector is an attack as opposed to a legitimate sequence. If an anomaly  
10 exists, the intrusion detection system signals an alarm manager to deliver an alert to the administrator in step 345.

If no anomaly is detected, the system interrogates the frame to determine if a pre-defined policy has been violated in step 340. Policy testing compares the observed activity with a configurable set of activity rules stored in the SDS. For example, a rule  
15 can declare that only specific hosts with specific addresses and specific network cards can access the network. If a pre-defined policy has been violated, the intrusion detection system signals an alarm manager to deliver an alert to the administrator in step 345.

The tests outlined above and depicted in FIG. 3 are performed serially. In other  
20 implementations, one or more of these tests may occur in parallel. Further, subsequent tests only occur if a prior test was passed. In a further implementation, all tests occur irrespective of the outcome of a prior test; consequently, a single read frame could potentially generate an alarm for every test performed on it.

Alerts can be in the any suitable form delivered to any suitable platform  
25 including, without limitation, a screen display to a monitor, a page to a pager, an outgoing voice call to telephone, a SMS message to a mobile telephone, an e-mail message to a valid address, posted to a Web page available via an appropriate Web server or WAP alert to a WAP enabled device. Various types of screen displays and reports may be used to provide information regarding generated alarms.

30 In one particular implementation referred to as AirDefense Mobile in U.S. Provisional Patent Application Serial Number 60/381,829 entitled "SYSTEMS AND

**ATTORNEY DOCKET NO. 093615600016**

METHODS FOR NEWTORK SECURITY" filed May 20, 2002, preferred interfaces for reviewing and reporting alarms are described in detail. The contents of this application are hereby incorporated by this reference herein for all purposes.

5 In some environments, the outputs of all IDS test are then compared and a confidence level computed in step 345. In one such, in the case where only a statistical anomaly is detected, it is flagged as a lower level performance alert. In the case where one or more other violations are detected, the alarm is elevated to an intrusion alarm.

10 Some environments may use a variety of data stores in implementing the above process to track data across multiple iterations of the process; such data stores can in one preferred embodiment be part of an SDS as described above. Some such environments can include a statistics database, a station database and/or a state data store. In such environments, some or all of the following steps depicted in FIG. 3 can occur.

15 In step 315, a station database is updated. This database contains, in one implementation, per station and per access point records with information describing device address, communications state, timestamps of first and last activity, counts of byte transmissions and local policy information describing whether device is authorized or not for usage in the monitored network.

20 In step 320 state information is updated. State refers to whether or not the device has been seen before and whether or not the station is unauthenticated and unassociated, authenticated, authenticated and associated or unknown state information associated with the wireless computer network.

25 In step 350, a determination is made as to whether a particular statistics interval has been complete. If so, statistics in an SDS are updated in step 355, and processing continues with the next frame in step 310. Otherwise, processing simply continues in step 310 with the next reading or receiving of a frame.

A modified and enhance version of the above approach is used where network traffic is monitored from multiple input devices such as with the configurations depicted in FIGs. 2B-E. FIG. 4 depicts this enhanced process starting at step 405.

30 Step 410 is analogous to step 305 from the process of FIG. 3. In step 410, configuration information is received. As before, this is typically done through reading

**ATTORNEY DOCKET NO. 093615600016**

system configuration files, monitoring the network and/or interactive entry at the outset of the process. This information typically includes network default data and risk criteria such as access point configuration data (MAC Address of the access point, Access Point Name, etc.), station configuration data and various thresholds values.

5        In step 430, a wireless packet frame is received from each input device (e.g., hardware components 210A-D, host system 220 and/or sensors 230A, 230B). Frames are read so that the frame content can be interrogated.

Each read frame is interrogated by a multi-dimensional intrusion detection system (IDS) such as detailed above with respect to FIG. 3, and the outputs of all IDS  
10       tests are then compared and a confidence level computed in step 435. As with the process above, other tests either alone, in combination with each other or in combination with one or more of those described above may be used in other implementations.

In step 440, in the case where only a statistical anomaly is detected, it is flagged  
15       as a lower level performance alert. In the case where, in addition to the statistical anomaly, one of the other violations has been detected, the alarm is elevated to an intrusion alarm and an alarm manger is alerted in step 444. Other implementations do not rely on aggregate test outcome but determine alarm status on single test outcomes. Further, some implementations can use other test types and outcome combinations to  
20       determine type and severity of alarms generated.

If an alarm is not detected in step 440, a test to see if a predetermined interval for gathering statistics has been reached occurs in step 460. If the end of the pre-configured statistics gathering interval has occurred, the SDS is updated in step 470 to reflect the statistics gathered from the received frames over the interval. Statistics are  
25       gathered by monitoring traffic between network nodes, minute-by-minute statistics about BSS frame types and traffic volumes, summaries of transmission statistics for all stations associated with access points, current-minute transmission statistics for all Stations, and detailed minute-by-minute transmission statistics for any individual station in the wireless computer network.

30       Data fusion occurs on a batch basis by aggregating data from multiple databases. This process begins at step 414. The process integrates statistical data from

**ATTORNEY DOCKET NO. 093615600016**

multiple databases that is generated through frame monitoring and intrusion detection engines. This approach provides a methodology for managing data received from input devices such as hardware devices 210A-D and/or sensors 230A, 230B deployed at multiple sites and for aggregating enterprise data at a single central system such as host 220.

The Attack and Station Profile database is read at step 418 to begin a processing loop to integrate databases from separate sources. Correlation and pattern recognition is performed at step 420 to update the attack and station profiles in step 424. The processing loop then sleeps at step 428 until the next processing loop interval is to take place based on the pre-configured time interval or trigger.

After the alarm manager is signaled in step 444, the attack and station profile database is read in step 448; in this step, existing attacks are queried and existing station security state is queried. In step 450, this data is compared to the newly generated alarm. If it is sufficiently similar, no new external notification occurs in step 454. If it is not, a new notification message is generated in step 454 and console display and/or external messaging of the alarm occurs in step 458.

In some environments, the scanning of air waves for network activity can be adaptive in nature. In a typical configuration, wireless network channels are scanned for activity according to a predefined pattern. According to an adaptive approach, the predefined pattern can serve as an initial and/or baseline pattern. This pattern can then be adapted based upon actual activity in the scanned channels.

This mechanism allows the system to deterministically scan all wireless channels through time-based multiplexing while also allowing the system to adaptively adjust the time spent on a given channel based on current and past activity. A typical scenario would be to monitor a fixed set of channels and periodically perform a background scan of the remaining channels; FIG. 14 depicts an example interface for configuring such a baseline or default scan pattern. If any activity is observed on a channel expected to be idle or unauthorized activity is discovered, the system adapts by adding this channel to its primary scanning pattern. If activity then diminishes, this channel will be removed from the primary scanning pattern and then scanned next during the background scanning mode. The system can utilize either pre-configured

**ATTORNEY DOCKET NO. 093615600016**

thresholds or user-entered thresholds to determine the trigger point at which to start or stop dynamic monitoring of the channel. Additionally, automated controls can be included that will lock onto the channel if a security violation has been detected per the underlying multi-dimensional analysis engine.

5           With reference to FIG. 11, the monitoring system is initialized in step 1110. Initialization in step 1110 can include the FIG. 4 configuration process and/or the step 910 initialization in FIG. 9 as previously discussed. After initialization, a primary network scan occurs according to a predetermined scan pattern in step 1115. A background scan can occur after each primary network scan. Alternatively, as  
10   depicted, a background scan may only occur based upon a particular trigger condition such as random determination, after a certain number of primary scan or after a certain time period has passed. A decision as to whether the particular condition to trigger a background scan has occurred is made at step 1120. In step 1125, the background scan occurs. A determination is then made in step 1130 as to whether an unauthorized  
15   device has been detected during the background scan. If not, processing continues at step 1115 with a primary network scan.

          If a device was detected, the scan pattern for the primary network is adapted in step 1135. This modified scan pattern is then used for scanning the wireless channels in step 1140. As above, background scans can occur after each such modified scan, or  
20   as depicted, can occur according to a trigger condition. In step 1145, a determination if fewer unauthorized devices were identified in the modified scan. If so, a determination is then made as to whether any unauthorized devices are still being detected in step 1165. If no unauthorized devices are still being detected, the scan pattern is reset to the predetermined original scan pattern at step 1170 and processing continues with a  
25   primary scan at step 1115. If some unauthorized devices are still being detected, the scan pattern is modified accordingly in step 1135 and processing continues with step 1140.

          If fewer devices were not found in step 1145, a determination is made as to whether a background scan should occur in step 1150. If not, processing continues  
30   with a further modified scan at step 1140. If so, at step 1155, the background scan occurs. A determination is made in step 1160 as to whether a previously unidentified

**ATTORNEY DOCKET NO. 093615600016**

unauthorized device has been detected. If so, the scan pattern is modified accordingly in step 1135 and processing continues with step 1140. If not, the processing continues with step 1140.

Those skilled in the art will readily appreciate that the described process is  
 5 exemplary and that the steps described need not occur in the exact order described but can proceed logically in other apparent orderings. For instance, the background scan determination loop in the modified scan portion of the flow could as readily occur before the fewer device determination step as after. Additional order alterations should be apparent and are contemplated.

10 Further, enhanced implementations may utilize multi-channel receivers in which adaptive scanning may occur uniquely per receiver. This allows, for example, multiple channels or multiple frequency bands to be scanned and monitored in parallel.

As described above, systems and methods described herein can automatically generate alarms whenever certain events or conditions occur within your wireless  
 15 network. In some such systems and methods, an alarm manager providing an interface for viewing can be provided; such an interface is described in greater detail in co-pending U.S. Provisional Patent Application Serial Number 60/381,829 entitled "SYSTEMS AND METHODS FOR NEWTORK SECURITY" filed May 20, 2002. The following table identifies the alarms, alarm subtypes and severities available in one  
 20 particular implementation referred to as AirDefense Mobile.

<b>Alarm Type</b>	<b>Alarm Subtype</b>	<b>Alarm Level</b>
DoS Attack	De-authenticate AirDefense Mobile detects when a hacker pretends to be an Access point and broadcasts a "de-authenticate" message. This forces all Stations to re-authenticate themselves, generating excessive network traffic, and causing inconsistent connectivity and data transfer.	Critical
	Disassociate AirDefense Mobile detects when a hacker pretends to be an	Critical

	will only generate an Ad Hoc Network alarm once in the current 24 hour period for each MAC address.	
AP Beacon Rate	AirDefense Mobile detects when an access point's beacon rate changed.	Critical

The present systems and methods allow an end-user to specify and implement the security and policy constraints associated with a particular wireless network deployment. Once configured with such information, the network activity is monitored on a continuous basis to determine if the activity is within the guidelines specified by the established constraints.

If the activity is found to not be in compliance with the established constraints, a real-time alarm is generated and reported to the user through a number of mechanisms. These mechanisms can include Web, Email, SNMP and Syslog notification. In some implementations, the response is not limited to notification. These implementations can include automated enforcement and/or active defensive measures as discussed below.

**Automated Policy Enforcement**

Some implementations support automated enforcement of constraints including, without limitation, thresholds and/or alarms. In such implementations, attempts to rectify the policy deviation through re-configuration of the affected device or devices can occur automatically upon detection of the deviation. This reconfiguration attempts to implement the specified policy within the relevant devices.

This process can be viewed as a form of a feedback control loop. In many cases, such a loop operates by comparing a reference input to a measured output, computing their difference, and using this difference to adjust the desired output. This continues to drive the desired output to compliance with the reference input.

FIG. 10 depicts an exemplary process that includes automated policy enforcement. An initialization step occurs to retrieve expected norms and configure data monitoring processes in step 1010. Normal monitoring of network activity occurs in steps 1020. The monitored activity is checked for compliance with established

**ATTORNEY DOCKET NO. 093615600016**

constraints in step 1030. If a violation was not detected, processing continues at step 1020.

If a constraint is violated, a notification (alert) can be generated and forwarded to a user and/or other systems (not shown). Such notifications can, in some instances, include information regarding the violation and/or one or more links that upon activation: (1) cause the display of information regarding the violation, (2) cause the activation of an interactive interface via which a user can attempt to manually rectify and/or manage the violation and/or (3) cause automatic attempts to wholly, or partially, rectify the violation. The notification can be sent via any suitable delivery platform as provided hereinabove with respect to alerts in general.

If a violation was detected, normal monitoring for additional violations can continue as depicted by simultaneously returning to step 1020 as well as proceeding to step 1040; alternatively, normal monitoring could be suspended until handling of the detected violation is complete.

The violation will typically have associated with it a set of one or more wireless network attributes. A procedure associated with the detected violation, and/or the attributes associated therewith, is triggered that attempts to manually, semi-automatically or automatically rectify the underlying cause of the violation. At step 1040 a communication channel is established with one or more devices associated with the detected violation, and/or the attributes associated with the detected violation. Commands to rectify the detected violation can then be sent to impacted devices in step 1050. The commands sent will depend at least in part upon the detected violation and/or the attributes associated therewith. At this point, the process may end in some implementations.

Some implementations may further make a determination as to whether the reconfiguration attempt was successful in step 1060. In some such implementations, the determination may include a determination of a success level indicating partial handling of the violation. Based upon the outcome of the determination, some implementations may make further attempts to correct, or complete the correction of, the violation through additional attempts to reconfigure the same or different devices as in the previous correction attempts. Step 1070 represents a decision as to whether

**ATTORNEY DOCKET NO. 093615600016**

further attempts should be made. This decision may rest on a number of factors including, without limitation, number of correction attempts, degree of success of prior attempts, appearance of additional issues resulting from prior attempts, etc.

If the attempt to enforce the policy is successful or unsuccessful, status  
5 information concerning the network can be updated in step 1080. For instance, if the procedure successfully, or partially successfully, rectifies the cause of the violation, any triggered alert or alerts can be cancelled, updated or otherwise modified to indicate the present status of the violation.

These steps can be executed upon a system processor or can be stored as  
10 executable instructions upon or across one or more computer readable media. Data used by the steps can be stored within the SDS described above. The communication channel established with the one or more devices can be made through one or more communication interfaces; such communication interfaces can be network interfaces, serial or parallel interfaces (e.g., USB, etc.), modem, or other suitable communication  
15 interface allowing communication between the system processor and the device.

Automatic resolution of the policy violation can employ a management and control interface on the monitored equipment to effect the desired change. This interface may be in the form of an HTTP, HTTPS, SNMP or vendor-specific command line interface reachable via Telnet, SSH or another remote login interface; in addition,  
20 or instead, alternative interfaces could be provided via automated voice and/or tone recognition systems for handling telephone based configuration of the environment. Multiple such interfaces could be simultaneously available. An example Web-based interface is depicted in FIGs. 13A1, 13A1a, 13A2, 13B1 and 13B2.

**Active Defense**

25 In some environments, one or more active defense mechanisms may be triggered in response to alarm conditions, in addition to, or instead of, the notification process described above. The system may provide active defense from attacks by broadcasting data into the wireless network as well as being able to trap and/or map an intruder's workstation by triangulating the position of the intruder's workstation  
30 relative to the wireless network access points. It also may attempt alter the access point

**ATTORNEY DOCKET NO. 093615600016**

configuration in a manner that makes it difficult or impossible for the targeted attacker to continue communications.

By introducing CRC errors into the wireless stream, the system can actively defeat an attacker that is monitoring the stream for patterns to crack the encryption.

5 CRC errors are introduced by transmitting at the same time as the detected intruder. Due the shared medium nature of the wireless computer network, the cause the packet transmission to be corrupted, preventing the intruder from successfully communicating with the network.

By introducing chaf, the system can actively defeat the attacker by placing

10 random frames into the stream so that the encryption pattern becomes undetectable. Chaf is a form of randomized packet transmission that is designed to reduce the probability that a statistical analysis of the packet sequence would result in breaking of the encryption key. This is done by emitting a low-rate background transmission of packets that are emitted using the same characteristics (e.g., address, initialization

15 vector, etc.) of legitimately observed traffic but with a randomized payload.

In addition, an active defensive measure can include de-authorizing a wireless station or access point, disabling a selected access point's wireless transceiver, and/or alerting an external network management system or an associated network component. In de-authorizing a wireless station or access point, the anomalous or unauthorized

20 station or access point is removed from the set of authorized wireless network components. In the case of disabling an access point's transceiver, a particular access point identified as unauthorized or providing access to unauthorized stations can have its wireless transceiver disabled in order to block further intrusion. In the case of alerting an external network management system or an associated network component,

25 the active defense measure involves coordination and data exchange between an attacked network and a central management system or component. This allows detection of higher level patterns in attempted intrusion. Such an alert could be transmitted in any suitable format including without limitation SNMP or an XML formatted alert.

30 Some environments may also include an adaptive location tracking component that locates and tracks identified stations and access points. In the case of unauthorized

**ATTORNEY DOCKET NO. 093615600016**

stations and access points, the detection and tagging for location tracking can be another form of active defense.

5 The system can lock-down a wireless network by jamming, a technique to prevent any unauthorized access to the wireless access point by introducing enough noise into the wireless network that workstations cannot physically connect to the wireless network. Jamming is a physical layer transmission that is performed to disrupt all unwanted wireless communications. It is equivalent to introducing a noise signal on top of the unwanted signal transmission such that any receiver would not be able to successfully receive the transmission.

10 The system can also lock-down a wireless network through logical jamming or disruption. In this case, unauthorized access is prevented through disruption at the communications protocol layer. This is done via use of standard network management, control and data messages.

15 In a Physical Device approach, one environment would utilize a standalone sensor to implement any of the Active Defense mechanisms. Dynamic channel change can be used to reroute authorized traffic to a different communication channel to avoid an intruder detected on a particular channel. In this approach, a channel change request is transmitted to the access point believed to be compromised and authorized stations use the new channel to communicate with the access point. This approach can also be used to avoid interference causing problems in communication between an access point and its authorized stations.

20 Some environments including dynamic channel change may further use a honeypot trap that tricks the attacker into thinking the original channel is still valid and provides the necessary forensic information to identify the attacker. FIG. 5 depicts a flow chart of a process starting at step 510 used in some such instances incorporating the honeypot trap.

25 In step 520, configuration information is received. This step is much the same as previously described steps 305 and 410 in FIGs. 3 and 4 respectively. Step 530 represents a waiting loop that waits until an attack has been detected. Typically, an intrusion detection system generates a signal that triggers departure from this loop; in some cases, the intrusion detection system contains the hardware and/or executes the

30

**ATTORNEY DOCKET NO. 093615600016**

process described above. The signal from the intrusion detection system typically includes an indicator of the access point believed to be under attack.

In the case that an attack has been detected in 530, processing is passed to step 540 to activate the honeypot trap. A trap thread is started in step 580; the thread  
5 initializes itself with the identity of the monitored access point believed to be attacked. This identity typically includes the MAC address, Service Set Identifier, encryption mode, network mode and transmission modes. Once initialized, the thread moves to step 590, the Trap Intruder process. This process is designed to logically fool the identifier attacker into believing communication is still occurring with the original  
10 access point. This is accomplished through complete emulation of the original access point's identity and behavior. By maintaining communication with the attacker, a trap is created such that the attacker's physical proximity is assured as long as communication continues. Optionally, a new identity may be assumed such that a weaker or more vulnerable appearing access point can be presented to the attacker.  
15 This is done by again emulating access point functionality, but in this case with an identity and set of characteristics that appear vulnerable. This vulnerability appearance may be created through the use of no or weak encryption modes or the appearance of default manufacturing modes with known passwords and user IDs.

In step 550 a control packet is sent to the original access point to change  
20 channels or suspend transmission while the trap is engaged. This packet encapsulates a message indicating the above request and may be sent in or out-of-band to the access point. In-band refers to over-the-air transmission to the access point's wireless network interface whereas out-of-band transmission refers to transmission to the wired side interface of the access point.

25 Processing in the main loop then returns to attack detection in 530.

In response to alarm activity or manual operation intervention, location tracking may be enabled to estimate the position of the desired device. This estimation is based upon receive signal characteristics and may include but is not limited to estimation based on time of arrival, differential time of arrival, angle of arrival or signal  
30 strength.

**ATTORNEY DOCKET NO. 093615600016**

In some implementation, triangulation determines the location of an attacker by mapping her relative position within the deployed wireless access points. An exemplary mapping and location detection process is depicted in FIGs. 6A-B and discussed in greater detail below.

5       The process of FIG. 6A is used to create an internal database of IP addresses and/or names mapped to corresponding MAC addresses. Every Address Resolution Protocol (ARP) transaction is detected in step 605. In step 610, the information in the detected transaction is used to update the internal database. Some implementations can perform the identification and location processing such as depicted in FIG. 6B without  
10       reference to such an internal database. This database is created and maintained in one implementation to make the station identification and location process easier and more efficient.

FIG. 6B depicts a process for identifying and locating a station within the wireless network. In some environments, this process can be used to pinpoint the  
15       location of a potential attacker; in some such environments, activation of the process is triggered by an intrusion detection system. In a particular implementation, the process is triggered by one of the intrusion detection systems and methods described in detail above.

In step 620, a lookup occurs in the internal database, such as created via the  
20       process depicted in FIG. 6A, on the current MAC address to determine if an IP or name mapping is already available. If found, the internal database is updated in step 640 and execution proceeds to step 645 to query the wireless sensor array--to begin position or location resolution. As indicated above, the internal database is one approach to acquiring the desired information. Some implementations may skip this step and use  
25       either the wired network sensor or the reverse address resolution protocol (RARP) approach discussed below.

Otherwise, an optional wired network sensor can be queried for the name mapping in step 625. This sensor is preferably deployed within the wired network at a location convenient to sniffing DHCP, LDAP, DNS or other service/name mapping  
30       protocols. If found, the internal database is updated in step 640 and execution proceeds to step 645 to query the wireless sensor array--to begin position or location resolution.

**ATTORNEY DOCKET NO. 093615600016**

Some implementations may not include such a wired network sensor; in which case this step is skipped.

If name is still not found, execution proceeds to step 630 where a RARP request is issued. This request asks the receiver population for the IP address of the MAC  
5 address in question. If found, the internal database is updated in step 640 and execution proceeds to step 645 to query the wireless sensor array--to begin position or location resolution.

If not found, name/IP mapping is not available at current time for this MAC address. In some environments, name/IP mapping may not be desired but location or  
10 position information is in which case the process can begin in such environments at step 645.

Step 645 begins the position or location resolution with a query to the wireless sensor array. Each sensor is queried for tracking information on the current MAC address in question. This tracking information identifies whether the MAC is currently  
15 observable by a given sensor, the sensor ID, and the signal strength associated with the MAC in question. The sensor array may include not only sensor devices (e.g., 230A, 230B) but also other wireless nodes accessible from this process such as devices 210A-D and/or host system 220.

From the data received via the query, the position relative to grid of sensors is  
20 calculated in step 650 by computing the "signal strength" distance to each sensor. This distance is computed as the square root of the sum of squares of three sensor signal strength values. The position is then estimated to be within the proximity of the sensors determined to have the smallest signal strength distance to the MAC address in question per the above computation. Once the set of sensors is selected, the position is  
25 further refined by selected the position as within the proximity of the sensor within above set with the strongest signal strength. In some implementations, the process ends at this point with the position information being returned.

In implementations maintaining a position database, this database is updated in step 660 with the position of the MAC address in question. The process then ends at  
30 step 670.

In some implementations, location tracking can be adaptive in nature. To facilitate the estimation and tracking of user location based upon pre-configured or dynamically determined criteria. This mechanism utilizes the sensor-based monitoring infrastructure to derive estimates of position based upon received signal characteristics.

5        In pre-configured mode, a static list of device identifiers representing the objects to be tracked is maintained within the system data store. As one or more of these devices become visible to the monitoring infrastructure, location tracking is automatically enabled and position estimates are automatically calculated and made available via the management, reporting and notification subsystems.

10        In adaptive mode, the tracking and position estimation of a given object is based upon some combination of operational and security assessments that the system automatically derives and assesses. These criteria may be based on time, traffic level, threat level, protocol characteristics, usage characteristics, etc. Once tracking has been engaged, it may be adapted based on continued monitoring of these criteria. Tracking  
15        may be engaged on a full-time basis, sampled periodically or ramped off over time. The level of tracking detail may also be varied dynamically depending on the above criteria, which can be used to drive the level of tracking granularity associated with a particular device.

      This feature facilitates the estimation and tracking of user location based upon  
20        pre-configured or dynamically determined criteria. This feature uses the sensor-based monitoring infrastructure to derive estimates of position based upon received signal characteristics. In pre-configured mode, a static list of device identifiers representing the objects to be tracked is maintained within the system data store. The list can be updated either automatically or upon user request. Automatic update can include time-  
25        based additions and/or deletions and/or event-based additions and/or deletion. In adaptive mode, the tracking and position estimation of a given object is based upon some combination of operational and security assessments that the system automatically derives and assesses, which could include an initial list of one or more device identifiers. These criteria may be based on time, traffic level, threat level,  
30        protocol characteristics, usage characteristics, etc. Once tracking has been engaged, it may be adapted based on continued monitoring of these criteria.

**ATTORNEY DOCKET NO. 093615600016**

Tracking may be engaged on a full-time basis, sampled periodically or ramped off over time. The level of tracking detail may also be varied dynamically depending on the above criteria, which can be used to drive the level of tracking granularity associated with a particular device.

5           A wireless device is identified for tracking. This identification is typically based upon one or more tracking criteria and/or device indicators, which in some instances are stored in a system data store. The tracking criteria can in some implementations include one or more of time, traffic level, threat level, protocol characteristics and/or usage characteristics. The tracking criteria can be statically  
10 defined or dynamically determined based upon network characteristics and/or configured preferences.

Tracking data is received from one or more wireless receivers; such tracking data can include signal strength data and directional data. The position of the identified wireless device is calculated based upon this received tracking data and outputted.

15           The position information can be outputted to any suitable output platform. Such output platforms can include, without limitation, e-mail, a web page, a facsimile, a graphic, an XML page, an SNMP message and/or a page. The target for the outputted position can be an end user or a further computer system.

In some instances, unauthorized wireless devices can be designated for dynamic  
20 identification and inclusion for tracking. RF characteristics for the identified unauthorized wireless device can be sensed and/or stored. In some cases, one or more additional sensors can be selected for collection of additional data to improve tracking performance.

The entire process can, in some implementations, be performed on a periodic or  
25 aperiodic basis. The periodicity of periodic performance can be according to a predetermined maintenance, reporting and/or analysis schedule and, in some implementations, can be adaptive based upon analysis schedule and/or various tracking criteria. Aperiodic repetition can occur as a result of an external request from a user or other system or upon occurrence of one or more predetermined events.

30           FIG. 16 depicts a process that facilitates the estimation and tracking of user location based upon pre-configured or dynamically determined criteria. This

**ATTORNEY DOCKET NO. 093615600016**

mechanism can use the sensor-based monitoring infrastructure to derive estimates of position based upon received signal characteristics. In pre-configured mode, a static list of device identifiers representing one or more objects to be tracked can be maintained within the system data store. In adaptive mode, the list of devices can be dynamically developed from an empty list or from a pre-configured static list. In some embodiments including an adaptive mode, a pre-configured static list can be provided that cannot be altered in adaptive mode; while in others, the objects in a pre-configured static list can be removed and/or modified just as objects dynamically added to the list of objects to be tracked.

10 First a wireless device for tracking is identified for tracking based upon data from the system data store in step 1600. As one or more of these devices become visible to the monitoring infrastructure, location tracking is automatically enabled and stations for tracking appear in a list in step 1605. Sensors are read in step 1606 and position estimates are automatically calculated in step 1607 and stored and/or made  
15 available via the management, reporting and/or notification subsystems.

In adaptive mode, the tracking and position estimation of a given object is based upon some combination of operational and security assessments that the system automatically derives and assesses. These criteria may be based on time, traffic level, threat level, protocol characteristics, usage characteristics, etc. The system tracks a  
20 wireless device in step 1605 through 1607.

When a rogue is detected based on selected criteria in step 1610, sensors are read in step 1615. The position of the wireless device is identified based upon the received data in step 1620. Once tracking has been engaged, it may be adapted based on continued monitoring of these criteria in step 1625. Tracking may be engaged on a  
25 full-time basis, step 1630 and then the sensors are read again in step 1615. Tracking may also be sampled periodically or ramped off over time. The level of tracking detail may be varied dynamically depending on the above criteria, which can be used to drive the level of tracking granularity associated with a particular device.

Referring to FIG. 19, an alternative process is depicted. Step 1900 performs  
30 much the same as step 1600 described above. Configuration information is read and a list of devices to be tracked is determined based at least in part on the read

**ATTORNEY DOCKET NO. 093615600016**

configuration information. A determination is then made at step 1905 if any devices to be tracked are listed. If not, configuration the process can repeat beginning at step 1900 either on a periodic basis or upon occurrence of an event such as a request from a user or another system.

5           If one or more objects are listed, these objects are tracked through reading of sensors at step 1910 and position estimation at step 1915, much as steps 1606 and 1607 described above. The position estimates can then be stored and/or made available via the management, reporting and/or notification subsystems. After listed items have been tracked, a determination is made as to whether a rogue object has been detected at step  
10   1920. If not, processing continues at 1900 as before on a periodic basis or upon event occurrence.

          If a rogue was detected, a determination is made as to whether dynamic rogue tracking is enabled at step 1925. If not, processing continues at 1900 as before on a periodic basis or upon event occurrence. If rogue tracking is enabled, the identified  
15   rogues is added to the tracking list at step 1930, sensor data is read at step 1935 and the location of the detected rogue is estimated and stored and/or made available via the management, reporting and/or notification subsystems at step 1940.

**Encrypted Network Analysis and Management**

          The techniques utilized to monitor WLANs can apply in general to monitoring  
20   and analyzing any network link using encryption of the payload or at the IP layer and above rather than just WLANs. In this case, Layer 1 and Layer 2 are observed and decisions made at these layers in terms of signature, protocol, policy and statistical anomaly analysis to assess network health and security. This technique is thus applicable to any network (wired or wireless) exhibiting the above encryption  
25   characteristics of the network traffic. In other words, the multi-dimensional IDS implemented per our framework is more broadly applicable to managing and securing any encrypted network. In this case, a WLAN running WEP is one particular instance of an encrypted network.
